ENTIRE HERD OF
Jersey Cattle
—PROPERTY OF—
Mr. Thomas R. Proctor,
AT AUCTION
At Bragg's Hotel Farm, UTICA, N. Y., TUESDAY, April 25th, 1899, commencing at 10 o'clock a. m. No postponement on account of weather.
PETER C. KELLOGG, Auctioneer.

Will sell to the highest bidder this entire registered herd of over fifty animals, which have for several generations been systematically bred for milk and butter production by the present owner, who has neglected no precaution to obtain bulls of deep producing strains, preferably Bunker, Stoke Pogis and Pedro, which blood permeate the animals to be sold, individuals among which have shown butter tests ranging from 14 pounds to over 23 pounds per seven days.

This herd, which is in excellent health and working condition, has won gold medals at the New York State Fair in 1887, 1888, 1889, 1892 and 1893, as well as several hundred premiums, may be inspected at any time.

For Catalogues, ready April 18, address:
PETER C. KELLOGG,
107 John St., NEW YORK.

THE JERSEY BULLETIN, Indianapolis, Ind.

and raise the calves. But how can the dairyman raise these calves successfully, if the whole milk goes to the factory to make cheese.

While the cheese factory is and has been of great benefit to the Canadian farmer, we believe it has been detrimental to the raising of good dairy stock in this country. For this reason we welcome the winter creamery, and the combined cheese factory and creamery that enables the farmer to get home a most valuable part of the milk in the early spring, which, if properly handled and supplemented with other foods, enables him to raise in the best way, cows for replenishing his dairy breed.

If none of our factories would make cheese till May 15, and would close promptly on October 31, of each year, we would not find the market over loaded in any year, and we would have a better quality of dairy cows in this community.

The butter situation continues favorable to the producer with a prospect of prices being well maintained for some time. For the past month or two we have not been depending so much upon the British market for an outlet for our surplus butter as will be the case later on. The local market has taken the bulk of the winter creamery, and at Montreal, last week, (March 25) 20 to 21 cents was freely paid by the local trade, figures which exporters could not afford to reach up to for fine, fresh creamery butter.

There has been, however, in spite of these favorable local conditions, considerable butter going forward. Every winter the number of persons engaged in the export butter trade increases. Many of the regular buyers in the cheese trade, during the summer, devote their energies, during the winter, to exporting winter butter. A couple of years ago all the winter creamery butter had to go forward on commission, the factories getting what remained after paying expenses of selling, etc. This year it is different.

The buyers and mostly those in Western Ontario, buy the butter outright from the factorymen, and send it forward at their own risk. Though there may not be any more money in this plan for the dairyman, than by sending forward on consignment, it certainly indicates a healthy state of affairs, and that those in the trade have confidence enough in the quality of the goods to invest their money and to run the risk of being reimbursed when the product arrives in Great Britain. J. W. WHEATON.

Toronto, Canada.

Would Like to do Better.

Thirty-eight Pounds of Butter Daily from Thirty-four Cows.—Capacity of Farm Doubled.

ED. HOARD'S DAIRYMAN:—Will you kindly formulate a balanced ration for grade Jersey cows weighing 850 lbs. from the following feeds: Plenty of corn ensilage from corn well eared, mixed clover and timothy hay in abundance, coarse wheat bran at $16 per ton; old corn meal at $16.50 per ton; cotton seed meal at $21.50 per ton.

I am milking 34 cows; of these, three are 2 years, and four are 3 years old, with first calf. Four others have not been fresh since last April and May. Four more fresh since Jan. 1, 1899, and all of the rest were fresh last Sept., Oct., and Nov. I am making from these 34 cows, 38 lbs. of butter a day; and would like them to do better if I can get them to by more judicious feeding. By the use of silos I am keeping 65 head where I formerly kept 35 head of stock. My limited success I owe to the teachings of HOARD'S DAIRYMAN. A. L. F.

New York.

No one yet knows what are the possibilities of production or profit from a herd of good dairy cows, but when such a herd as our friend describes is producing the amount of butter stated, the evidence is well nigh conclusive that there is no radical defect in care or feeding, and that further improvement must be looked for in a careful study of each animal and her performance, and adapting general principles to their individual capacities. This is something that only the owner or herdsman can do, and he, intelligently, only when he keeps a daily record of the feed and its results.

When we learn, as we do, from the reports of carefully conducted experiments that one cow will yield $40 profit, while a stable companion, with equal opportunities will yield only $20, or $10, or sometimes not pay for her feed, it is plain that no man is wise enough to suggest a ration that can be fed without variation to all the cows in a herd. It does not follow that ration formulas are therefore useless; far from it. Unless we discard the voluntary testimony of thousands of our readers, the formulas we have given in the last six years have been of incalculable help, both directly and indirectly. Some have been followed to the letter with benefit quite beyond our reasonable expectations; others have awakened a spirit of inquiry and study and a determination to adapt means to ends, which have made the feeding of dairy cows a science when it had formerly been only a chore.

Had we such a herd as our friend reports we should expect to feed each cow about 30 lbs. of silage and 10 lbs. of the mixed hay daily; to this we should add grain according to the ability of the individual to respond, having regard to age, natural ability and stage of lactation. The average would probably be the equivalent of about 6 lbs. of bran and 2 lbs. of cotton seed meal. If in any case, it seemed desirable to feed more grain than this we would use the corn meal up to 3 to 4 lbs. and beyond that, corn meal and bran in equal amounts. In reducing the grain we would first cut down on the cotton seed meal, dropping off gradually until it was reduced to less than one pound and then commence on the bran.

The price quoted for cotton seed meal suggests that it is relatively very cheap or of inferior quality.

Hand Separators.—Raising Calves.

ED. HOARD'S DAIRYMAN:—On page 95 of Volume XXX in HOARD'S DAIRYMAN, R. M. G. asks for information regarding the use of a hand separator. My experience with milk, taken to a factory to be separated, is precisely as R. M. G. says; it returns sour and unfit for calves.

I have used a separator over three years, and my practice is to skim the milk immediately after milking, before it becomes too cool, and the calves are fed the warm skim milk in which there is not a trace of fat visible. It is a thing of beauty and a joy forever, to see the calves; not much like sour factory milk fed calves.

This milk from the hand separator has its natural warmth left, which is different from artificial heat. I can say from experience, that calves do much better on this separated milk, with its natural warmth and not a trace of butter fat, than they would on sweet skim milk artificially warmed with as much as 1% of fat left in it.

I consider that my herd of twenty cows, which consists of registered and high grade Jerseys, paid for my separator in less time than a year, on extra value of dairy calves raised.

Perhaps a word of my experience, in raising calves for the use in my dairy, would not come amiss. I have always been very particular in keeping in my mind the words I so often heard Prof. Henry express, while attending college, and reviewing feeds and feeding with my class. Every now and then the Professor would say; "Don't get a calf you intend raising for the dairy, fat;" and then he would remind us that there was no feed that would take the place of whole oats, for a calf drinking milk. It seems to be something the calf's stomach needs to keep it healthy.

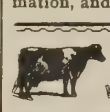
With these two things in view, I have been very successful in raising choice dairy cows from my heifer calves. I have small stanchions, with a tight manger in front for feeding. When the calves hear the buckets, from which they drink, taken from the shelf, they are all anxious for their share, and each calf finds its way into one of the stanchions, and all there is to be done is to close it, and put a peg in to hold it in place.

I have each calf tied for the time being, and each one gets its share of milk. When they are through drinking, they get a feed of whole oats, which they learn to eat while very young, from their place of confinement. When they have this nearly cleaned up, I give them whatever they are to have in the line of coarse feed, which, usually, is second cutting of clover hay.

They have forgotten that they just drank milk, and will commence munching down the hay; then they can be loosened, and never a calf will think of such a thing as sucking noses or ears, and thus allow the larger and stronger ones to get full benefit from the hay, while they are thus enjoying themselves to no good. Anyone accustomed to feeding calves in an open way, will readily see the benefit derived from feeding in stanchions.

As I always have my calves come in the fall of the year, I feed them through the winter, and in the spring turn them out to pasture; thus they are one year old at the beginning of their second winter. If it would benefit anyone, I would gladly give my experience and practice with them up to the time I have mature cows, giving me a herd test of from 6 to 8% butter fat. C. D. B.

Tomah, Wis.



We should be glad to have C. B. D. give us more of his experience.—Ed.

SPRAYING FRUIT TREES.

The question of spraying fruit trees to prevent the depredations of insect pests and fungus diseases is no longer an experiment but a necessity.

Our readers will do well to write Wm Stahl Quincy, Ill., and get his catalogue describing twenty one styles of Spraying Outfits and full treatise on spraying the different fruit and vegetable crops, which contains much valuable information, and may be had for the asking.

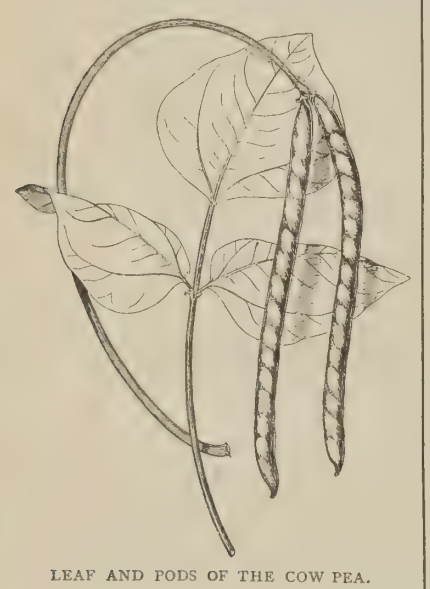
Cow Peas.



The cow pea is to the South what alfalfa is to the West and red clover to the North—a forage plant well adapted to the needs of the region. The cow pea has been cultivated in the South for at least one hundred and fifty years. It was probably first introduced on plantations in South Carolina, the seed having been brought from India or China. From this original introduction and from subsequent importations its cultivation has spread to almost every farm and plantation in the Southern States.

Cow peas are in their relationship and habit of growth really beans and not peas, as the name would indicate. They are annuals, belonging to the genus *Vigna*, the members of which are largely represented in South Africa and are closely related to the lablab, lima, and haricot beans of our gardens, as well as to numerous cultivated or half-wild garden sorts common in tropical Asia and America, but little known to us.

VARIETIES.

There are a very large number of named varieties of this forage plant. New forms are constantly arising, due to variations in the habit of growth, color of leaf, stem, and pod, and the shape and color of the seed. Variations from any chosen type are constantly appearing, and as one or another of these sports or forms gains sufficient local reputation a new name is applied, and sooner or later the supposed new variety is placed upon the market. In this way one variety of cow pea may be cultivated in a dozen different localities under as many names, or a dozen different peas may bear the same name.

Cow peas occur in every gradation of habit, from a compact, stocky, upright bush having single stems a foot high with very short lateral branches, to those with trailing runners growing as flat upon the ground as sweet potato or melon vines, the prostrate stems 15 to 20 feet in length. The pods vary from 4 to 16 inches in length, and the peas are of every imaginable shade of white, yellow, green, pink, gray, brown, red, purple, and black, of solid colors or variously mottled and speckled, and of varying sizes and forms, from large kidney-shaped to little round ones smaller than the garden pea.

LEAF AND PODS OF THE COW PEA.
(*Vigna Catyang*)

There is a like variation in the length of time the different forms require to ripen seed, some requiring eight or nine months, a few ripening in sixty days from the time of planting.

There seems to be a somewhat constant relation between the time required for attaining maturity and the habit of growth. The bush varieties ripen in a shorter season than the trailers, but a bush variety taken from Tennessee or Virginia will, in the course of a few seasons, assume the trailing habit, and lengthen out its period of growth, when removed to the Gulf States. Also, a runner or creeper requiring six to eight months for reaching maturity in Louisiana will, if planted each year a hundred miles farther north, gradually accommodate itself to the shorter season and at the same time shorten its runners, approaching more and more to the upright or "bush" habit of growth. No definite line of separation can be drawn between bush peas, trailers, and runners. The best varietal character is probably the color of the seed. It is quite probable that more than one species is in cultivation. The "red" and "black" varieties are closely allied; the round "lady" peas form a separate group; the large "black-eyed" and "purple-eyed" are typical of another, and the variously mottled and speckled "whip-poor-wills" are only a degree removed from the solid-colored yellow, pinkish, and light brown ones, and together would naturally be taken to constitute one species or variety. The black peas pass through various shades of red before maturity. The red varieties sometimes carry their change of color in ripening so far that they can not be distinguished from the black. The "black-eye" and "purple-eye" are of the same ground color, differing only in the color of the ring surrounding the eye. The various "crowders", yellow and white, the whip-poor-will, clay, and "yellow-eye" forms have numerous crosses and so-called hybrids in which the fundamental yellows and browns form varying mixtures.

COW PEAS FOR FORAGE.

There is no forage plant better adapted to the needs and conditions of Southern agriculture than this rank, free-growing annual. It will thrive luxuriantly upon the rich, swampy, cane lands of Louisiana. On the driest and most sterile worn-out uplands it serves the admirable purpose of supplying a larger quantity and better quality of forage than any bean or clover. And whenever a crop of cow peas has been taken off a field, the surface soil is left richer by a good many pounds of that most costly of all plant foods, nitrogen. The roots of the cow pea enter deeply into the soil, opening and loosening it far down for the benefit of the roots of the succeeding crops of corn, cotton and tobacco. It has been found by experiment that the fertilizing value of the roots and stubble of the cow pea are very considerable, but not as great as that of the hay removed from the field. The best and most economical use of this forage crop is, then, to cut for hay, feed to stock, and return the stable manure to the soil. Plowing the whole crop under is less remunerative, because there is much needless waste of the muscle-making and fat-forming constituents of the plant which would bring more profit if turned into beef, pork, wool, cheese or butter.

METHODS OF CULTIVATION AND HARVESTING.

Cow peas are planted broadcast or in drills, very commonly between the corn rows, after the crop is laid by. The amount of seed used varies from four quarts to two bushels per acre, the average amount being, perhaps, about three pecks. If sown in drills, eighteen to thirty inches apart, less seed is required then when sown broadcast. The seed will stand being covered to the depth of two or three inches, but care must be taken to plant when the ground is neither too wet nor too cold, as the peas rot very rapidly under such circumstances. In regard to excess of moisture, cow peas behave like beans, and in the early stages delight in a warm, mellow seed bed. Much of the failure that has attended the attempted introduction of cow peas into the Northern states is due to planting before the ground is warm enough. It must be remembered that this plant originated in the Tropics, and that when transplanted to higher latitudes, it makes its best growth in the hottest weather. It is even more susceptible to cold and wet than is corn. Hence, proper delay in planting will permit economy in the use of seed. Where the vines are grown for hay, the yield will be larger if the seed is planted in drills, and cultivated a time or two. The yield of peas is also larger when only a moderate amount of seed is sown, and the vines have more space, and light, and air between them. It is also heavier from late-planted vines than from the very early ones. In tests to determine the relative value of different named varieties, it has been found that, as a rule, those which make the heaviest yields of vines also bear large crops of peas.

The vines should be mowed for hay when the peas are well formed, and the leaves and pods are first beginning to turn yellow. After wilting on the ground, or in windrows from twenty-four to forty-eight hours, the hay is placed in small, thin piles or cocks, and allowed to cure for several days, when it may be carted to the barn, or stacked under sheds. The hay making process is a difficult one, requiring more care and attention than in the case of red clover, because the broad leaves and thick stems contain a larger amount of water. The hay must be placed in cocks before the leaves become brittle, and the piles must be small enough to allow free circulation of air to the center of each. Bright cow pea hay, clean and well cured, is worth as much as the best red clover hay, and there is no good reason why the Southern farmers and planters should buy the Northern grown article for their working stock, or for fattening their cattle. Every ton of hay used on the farm should be grown there. Another method of curing hay, is to stack the vines in a pen, or rack of rails, or poles so arranged as to allow the air to enter every part of the pile. This stacking over poles is best, where the vines are pulled, or where the trailing and creeping sorts are

Always Use the BEST.

The temptation to try a cheaper article in manufacturing high grade goods is such that the experiment is often undertaken and results generally in producing an inferior article.

High grade butter needs the best of appliances and skill and particularly the best Color.

WELLS, RICHARDSON & CO.'S IMPROVED BUTTER COLOR

has maintained its reputation as the best. It is always reliable and gives the true June shade.

"THE KIND THAT HAS NO MUD."

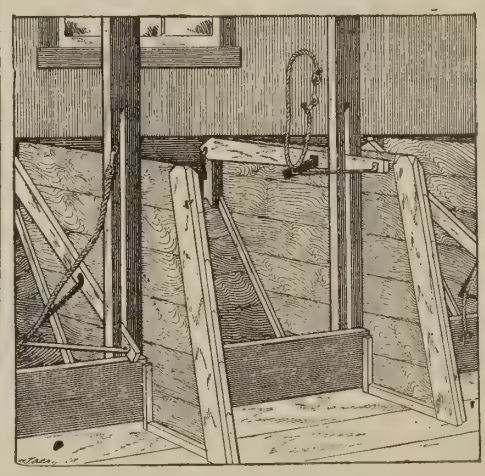
SEARS, ROEBUCK & CO., CHICAGO, ILL.



For $1.00 we furnish a Gas Lamp, the exact same lamp as is now being widely advertised as a premium with a bicycle as a Regular $4.00 Acetylene Gas Lamp, but we do not guarantee or recommend it.

ILLUSTRATION.

This new device for hitching cows is creating no little talk among dairymen, and we take pleasure in furnishing our readers a description of it.

ORIGIN AND HISTORY.

Mr. Willard H. Knapp, of Cortland, N. Y., first constructed it in his barn, in December, 1897, as an experiment. For several years he had been especially interested in the breeding of registered Jersey cattle and the proper care of stock, and fastening same in stables. The old-time, stock-like stanchions were inhuman, and he consequently decided to discard them. In considering devices of a more humane nature, the idea represented in the accompanying cut suggested itself. It was constructed and put in actual use. The appearance of the herd in the barn was greatly improved. The cows gained in flesh, and the quantity of milk increased. Mr. Knapp was well pleased with the experiment.

As will be seen by glancing at the cut, the device consists of one short and one long upright, with an elongated opening in the latter. A horizontal arm, pivoted to the short upright, passes through the opening. To that arm is fastened an angle iron, to which is attached a strap, rope or chain. It will readily be seen that when a cow is standing, she is pushed back to the gutter, and when lying, drawn forward; thus conducing to the cleanliness of the animal.

The partitions are an important feature. There is no farmer, who would knowingly feed all cows alike, no matter what might be their physical condition or work. No dairyman should feed all cows alike. One animal will require a different food from that of her neighbor. Again veterinarians have oftentimes stated that germs of disease are spread among cattle on account of their securing each others food.

In the "Willard Knapp Cow Tie", the partitions so divide the feeding trough, that an animal eats only the food designed for her, and can in no way reach for and secure that designed for her neighbor.

If one prefers, the partitions may extend back as far as the gutter, in order to prevent the cows from injuring one another.

Much is being said at agricultural meetings, and written in the agricultural press, regarding the cruelty of fastening cows in the old stock-like stanchions. We are in sympathy with whatever has been said against the stanchions. Farmers are fast realizing the importance of discarding the old time stanchions, and using humane, comfortable, up-to-date devices. It will certainly pay the readers of HOARD'S DAIRYMAN to investigate the question of fastening cattle.

The "Willard Knapp Cow Tie" is a humane, inexpensive, practical and durable device. It promotes cleanliness, comfort and health.

Mr. Knapp had no thought of putting his device upon the market, until urged to do so by many prominent agriculturalists, of New York state, who saw in it a long felt want.

Willard H. Knapp & Co., Cortland, N. Y., manufacture the frame work for this device. Circulars with up-to-date testimonials, from up-to-date men, will be mailed free upon application.

used. The bush varieties are the best for hay, because of the greater ease with which they may be mowed and handled. They also hold their leaves better than the ranker trailing sorts. The yield of hay varies according to the fertility of the soil upon which it is raised, whether it is grown on rich lowlands, or on the drier and more sterile uplands. In the Gulf States, cow peas will probably give an average yield of two to three tons per acre, while four to six tons are not uncommon. Farther north the average will range from 1½ tons in Ohio to 2½ tons in Arkansas, Missouri and Tennessee. As with other crops, the time of planting, the character of the soil and of the cultivation, and the amount of rainfall have much to do with the yield. Along the Gulf it is one of the best hay crops. North of the latitude of the Ohio river it is chiefly valuable as an addition to the list of drouth-resistant, soiling crops, and as a crop that will yield a considerable amount of forage on soil too sterile to grow red clover. The commercial value runs from $6 to $20 per ton, being governed by the relative abundance of other grades of hay and fodder. Its feeding value is equal to that of the best red clover, and the hay ranks high in palatability and digestibility.

HARVESTING THE SEED.

The majority of farmers harvest only enough seed of cow peas to plant again the next season. The ripe pods are picked by hand and are stored in barrels until needed, or are thrashed out by machine or with flails on the barn floor during the winter. Sometimes, if the crop is heavy enough to render it profitable, the vines are run through an ordinary threshing machine from which the concaves and alternate teeth of the cylinder have been removed. But a machine breaks and bruises more of the seed than when the pods are first picked off by hand. Fully 95 per cent of the seed placed upon the market is hand picked. The yield per acre varies according to the variety and the method of cultivation. Eight to twelve bushels is a fair average of the amount that can be obtained when the peas are planted in the corn rows. Sown alone, broadcast or in drills, yields of from twenty to thirty five and even in rare cases, fifty bushels are obtained. The Black, Unknown, Red Ripper, Clay, and Calico varieties are all heavy seed bearers. Lady and White Crowder are good for table use and also yield well. The Black-eye, Red Crowder, and Whip-poor-will, or Speckled, are very widely cultivated and find ready sale. Those which make the larger growth of vines for green manure, as a winter soil mulch, for hay or soiling are the Unknown, Red Ripper, Southdown, and Clay. Whip-poor-will, Black-eye, White, and Red Crowder ripen in from twelve to fourteen weeks, and hence are adapted to cultivation farther north than the very late, but ranker growing, Unknown, Wonderful, Red Ripper, Black and Gourd varieties The New Era and Lee ripen seed in from six to eight weeks, and hence are the ones to recommend for summer soiling crops in the upper prairie region of the Mississippi Valley or any where else that an early maturing cow pea is required. This is one of the species of cultivated plants which is very readily modified by change of habitat. Early and late maturing forms may be found of every strain that has been in cultivation for any considerable time.

THE FEEDING VALUE OF COW PEAS.

The feeding value of cow pea hay is very high, as shown by feeding tests and chemical analyses. Berckmans states that the well cured hay is more nutritious than any hay produced from grass, millet, or any other plant used for the purpose, and that one ton of it will last as long as a ton and a half of the best timothy. One hundred pounds of the green vines contain 16.4 pounds of total dry matter, of which ten pounds are digestible. One hundred pounds of the hay contain 89.3 pounds of the total dry matter, of which 50.7 pounds are digestible. The digestible crude protein in the hay amounts to 10.79 pounds in comparison with 10 58 for alfalfa, 10.49 for crimson clover, 6 58 for red clover, and 2 89 for timothy. The digestible carbohydrates and fat amount to 39.91 pounds in every 100 pounds of cow pea hay, 38.71 for alfalfa, 39 42 for crimson clover, 37.01 for red clover, and 45.15 for timothy. The average nutritive ratio of cow pea hay is 1:3.9; of alfalfa, 1:3.8; of crimson clover, 1:3 9; of red clover, 1:5 9; and of timothy, 1:16.2. The green cow pea vines are more succulent than red clover or any of the grasses, containing less dry matter per total weight.

The feeding value of the hay is shown by the nutritive ratio which represents the relation of the digestible crude protein to the carbohydrates and extract matter. Thus, for every pound of digestible crude protein in cow pea hay there are 3.9 pounds of digestible carbohydrates and fat. In order to insure uniform growth of an animal and get the full feeding value of all the constituents of a forage, the ratio must be properly balanced. The nutritive ratio of cow pea hay is narrower than can be properly utilized by the animal, and to get the full benefit of all the crude protein in the plant, hay or coarse fodder containing an excess of the carbohydrates must be added to the daily ration. A practical farmer, writing from Southern Mississippi, says that excellent results were obtained through feeding two parts of cow pea hay to one part of crab grass or timothy, and when using this ration very little grain was required, especially when the hay contained much of the pods. If cow pea hay be fed without the admixture of some coarse forage or grass hay, a portion of the protein will be wasted through inability of the animal to digest and assimilate the whole amount. Cow pea hay is used on many of the Southern sugar and rice plantations for the horses and mules, and it is found that work stock keep in excellent condition upon it, requiring very little grain.—*Farmers' Bulletin, No. 89, United States Department of Agriculture.*

Gasoline Engine for Separator Work.

ED. HOARD'S DAIRYMAN:—I am contemplating putting in a gasoline engine to run cream separator and churn. I noticed in issue of March 17, of the DAIRYMAN, page 93, an article by Mr. McKinnon rather against the gasoline engine for separator work. I would be pleased to hear from other parties on this subject, as I do not wish to make a mistake in purchasing. We make butter the year round and I would prefer the gasoline in preference to steam in this cold climate, provided the gasoline would do good work. W. D. BLOUNT.

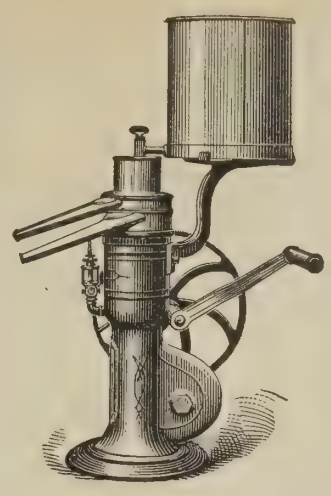
Oswego Co., N. Y.

The use of gasoline engines for separators has been favorably spoken of by several correspondents, in the back numbers of the DAIRYMAN; no objection having been found to them on the score of irregular motion. The only objection urged is to the want of hot water and steam in the dairy where they are used, but this is easily obviated by the use of a small heater. Or the water can be heated by the waste gases from the engine.

When a mother thinks she is going to die and rather wishes she could, what happens to the child? Where else shall the child get the love, kindness and care that is to ripen it into useful, happy maturity?

Where is the husband to turn for the comfort of home—the sympathy of wifely affection—the support that only a strong, cheerful, healthy help mate can give?

Who is to be pitied most? Mother—father—child?



Whose fault is it?

Nobody's maybe — certainly not the child's. Either the mother or father can write to Dr. Pierce and receive medical advice free. Thousands have done it. Thousands of homes have been made happy by it. Thousands of weak women suffering with the pains and debilitating drains of a diseased condition of the distinctly feminine organism have followed Dr. Pierce's advice and become again blooming, vigorous, loving, cheerful and loved.

Dr. R. V. Pierce is chief consulting physician at the world-famous Invalids' Hotel and Surgical Institute, at Buffalo, N. Y., and during his thirty years' practice here developed his great family medicines—Dr. Pierce's Favorite Prescription, Dr. Pierce's Pleasant Pellets, Dr. Pierce's Golden Medical Discovery.

Mrs. Claus Nelson, of Pico Heights, Los Angeles, Cal., Box 31, writes: "I send you my picture taken with my little boy. I do not look so sad now as I do in the picture; I was sick then and I thought my days would not be long, but your kindness and medicine would not let me die. You have my heart-felt thanks for your kindly advice to me in my sickness; also for your book which I received two years ago, and which I could not do without. It is all the Doctor I have had since I got it. I had female trouble, and Dr. Pierce's Favorite Prescription, together with the advice given in his book, cured me of five years' sickness."

The book Mrs. Nelson mentions is Dr. Pierce's 1,000 page "Medical Adviser," the most useful "doctor book" published. A copy in stiff paper-covers sent on receipt of 21 one-cent stamps to pay expense of mailing *only;* in cloth-binding ten stamps extra. Dr. R. V. Pierce, Buffalo, N. Y.

Building up a Dairy Herd.

Good Selection. Good Feed.—Good Sires.

ED. HOARD'S DAIRYMAN:—I send you the record of our dairy for 1898. It is not a phenomenal record, but it is a very fair illustration of the work of building up from common stock a good working herd by breeding, selection, and care.

The dairy consists of eleven grade Jerseys. The record includes nine, as it was expected to dispose of two of them during the year.

Name.	*Age.*	*Milk lbs.*	*Test.*	*Butter fat.*
Tilly.....	11	65 9	4.90	320
Blackie....	5	4675	5.25	245

Thankful..	3	4181	4.80	201
Dotty.....	5	4668	4.70	2 9

The same strain of cows has been in the family for fifty years. The original cow, from which the herd descended, was brought on to the farm as a part of a weedding dowry. How long the same breed of cows had been in the grandfather's family, no one knows. The cow was a native with good form, vigorous constitution, and large milking qualities.

For many years the raising of steers was foremost and the production of butter secondary. When, however, horses largely took the place of oxen, this kind of farming became less profitable and the dairy was gradually increased.

About twenty years ago the last remaining descendant of the original stock was bred to a Jersey bull. The result was a heifer calf which, as a mature cow, produced over 500 pounds of butter in one year. This cow brought us seven heifer calves, never having any others and dying of milk fever when eight years old. All of these calves were grown up to mature cows and proved to be good. They made a good foundation for a dairy. Two of them still remain in the herd.

Ever since beginning to breed to the Jerseys we have practiced weighing each cow's milk occasionally. Before the Babcock test was invented we tested the quality of each cow's milk at intervals by setting the milk for a day and churning the cream.

In making the record given above, we weighed the milk from each cow the first and the fifteenth of each month, averaging these with the first of the following month. Each cow's milk was tested twice during the year by the courtesy of our local creamery. The tests represented composite samples of four consecutive milkings.

Some of these tests are very interesting when it is remembered how closely related these cows are and how many generations they represent. The two cows above referred to, although own sisters, test on an average, one 4.30%, the other 5.40%.

Four cows, all about the same length of time in milk, tested as follows: The daughter of the first cow that was bred to a Jersey 4%; the granddaughter 4.2%; the great granddaughter 4.4%; the great great granddaughter 5.2%. Whether this latest candidate for dairy honors can be brought up to a generous flow of milk, remains to be seen. In all of these cases there were no abnormal conditions making the milk richer or poorer. It was simply the difference in the cows.

In grading up the herd, the plan has been to use as good sires as could be had at moderate expense. We have not practiced inbreeding, but when it has been necessary to change, have tried to do a little better each time. The present head of the herd is out of a cow which was claimed to have made two and one half pounds of butter a day for one-hundred consecutive days. The cow has a good line of ancestors reaching back to the famous Jersey Queen of Barnet, in Vermont.

Our cows are fed twice a day and watered once. Their feed in winter consists of ensilage, night and morning, and timothy hay with much too small a proportion of clover. Their grain ration at present is made by mixing 100 lbs. of bran with 50 lbs. of cotton seed meal and 25 lbs. of Chicago gluten meal. Of this mixture from 2 to 4 lbs. a day is fed according to the length of time a cow has been in milk, her condition and performance at the pail.

In summer some corn meal is substituted for some of the more nitrogenous meals and only about half the quantity is fed. Short pasture is supplemented during the flush of feed by hay and later by rowen, sometimes peas and oats, and when mature enough, by corn.

We are aware that the grain ration is small, not sufficient to balance properly the roughage. But situated as we are, four miles from the railroad and in a hilly country, we have bought less concentrated feed and depended more upon home grown fodders. We have usually found that the cows respond more generously to good pasture and early cut hay than to an increase in their concentrated feed.

A "Baby" separator No. 3 is used to skim the milk. The separator milk, while still warm, is fed to pigs and calves. All of the latter are raised—the heifers to be grown up into cows, the males for beef when eight or twelve months old. The cream is taken twice or three times a week to a co-operative creamery. The past year the creamery has paid its patrons 20½ cents per pound for butter fat.

Washington Co., Vt. A. N. BLISS.

A Nebraska Holstein Record.

ED. HOARD'S DAIRYMAN:—Seeing almost weekly representatives of the Holstein-Friesian cow as a milk and butter producer, I thought it might interest some of the DAIRYMAN readers to see a record of a thorough-bred Holstein-Friesian cow, 5 years old, owned by me. Her record of a ten-months' milk and test, as taken from a record taken up by the superintendent of the creamery station here, is as follows:

The record is from October 1st, 1897, to July, 1898. Milk, 16,300 pounds with an average test of 4 per cent fat, by the Babcock test. This is from three milkings daily, after having been fresh for two weeks, before selling my milk at the creamery. I got an average price of 16 cents.

I do not feed rations; my cows have all the millet hay they wish, when out in the lot, and all the alfalfa hay they wish when taken in for the night. I feed 14 pounds of corn and cob, ground, per day. This cow is a hearty eater, and will show extra feeding in the milk pail. I think the Holstein-Friesian cow the best for making dairying profitable, and improving other breeds. For milk quantity there is no equal, as I have some mixed grades besides my thorough-bred that give 50 pounds of milk daily.

Lancaster Co., Neb. H. F.

THE COW AND HER PROFIT.

A number of years ago Hon. J. H. Walker of Mass., made the following calculation:

"If butter be worth thirty cents per pound and it costs $35 to keep a cow, the farmer or dairyman paying:

	In ten years.
$ 30 for a 200-lb. cow realizes.....	$182.87
125 for a 300 lb. cow realizes.....	354.78
250 for a 400-lb. cow realizes.....	483.49
350 for a 500-lb. cow realizes.....	654.17
450 for a 600-lb. cow realizes.....	811.69

It will be seen that the highest priced cow pays very much the largest profit and the chances of her doing business ten years is probably about as great.

THE SCRUB BULL.

A correspondent of the *Nebraska Farmer* describes the scrub bull in the following quaint verse:

"His sire was mean and mean his dam,
And damned to all Eternity
By neighbors sad and neighbors mad,
Whose damns meant not maternity."

IOWA STATE DAIRY ASSOCIATION.

The executive committee of the Iowa Dairymen's Association have voted to hold the next Annual meeting at Mason City, Nov. 15, 16 and 17, 1899. Persons interested in this event should make a note of the place and date.

CONCERNING OUR ADVERTISERS.

"IT HAS NEVER FAILED YET."

WHITEWATER, Wis., Dec. 1, 1898.

The Lawrence-Williams Co., Cleveland, O.:

I have been using your Gombault's Caustic Balsam for ten years, for different ailments. It has never failed for me yet; also used it for human ailments. Can you furnish me with Caustic Balsam direct from you? If so, please write me prices and terms. DR. HIGLEY, V. S. D.

Note the ad in this issue of Drown Stall Co, Madison, Wis. This stall has been spoken of very highly by HOARD'S DAIRYMAN many times in the past and we know of none on the market to day that has met with more hearty approval by users than this stall. Those who use it have the most to say for it. We receive a great many letters making inquiry in regard to cow stalls and we are free to say to all that no better reference can be given than to the Drown cow stall.

VETERINARY.

Queries in this department answered by WM HORNE, M. D. V. S., Janesville, Wis.

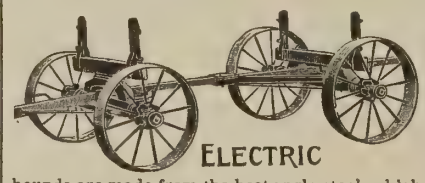
COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

HYPODERMIC TREATMENT FOR ABORTION.

Do you think the hypodermic method a good treatment? If not, what objection to it? I keep from 70 to 76 cows; have had abortion in my dairy, more or less, for quite a number of years. For about three years have stopped buying; raising my own calves; since which time my old cows seem to be free, or nearly so, from abortion, and my heifers nearly all abort with first calf on third to seventh month. I use some disinfectant and syringe for some weeks after abortion, and nearly all come right the next year. I have studied abortion for more than ten years, many cases of my own and my neighbors have come under my notice. Have also noticed for some years the articles in HOARD'S DAIRYMAN on this subject. Have used treatment of Fuller & Co., Lowell, Mass., with some good results. Heifers run in a back pasture, away from my cows, and are served by a separate bull, a yearling. Heifers are stabled in an ell to main barn, but more or less passing back and forth from main barn, so are not entirely exempt from any air odors, etc., one barn to the other, although the young cattle are yarded separately. Most of the abortions have occurred in barn, one or two each for the past two years in pasture, where young cattle were. R. A. W.

Poultny, Vt.

ANSWER.



From your own statement you seem to be doing well. Hypodermic injections are fallacious. They are not a remedy for abortion.

SPINAL MENINGITIS AND SILOS.

Since last Christmas I have lost three good farm horses with spinal meningitis (generally called putrid fever or putrid sore throat), one of them, our family horse that my wife and children could drive anywhere. It seems to be a disease which the veterinary surgeons have not mastered, and do not positively know the cause, although the different ones I have consulted think it is caused by germs taken into the system in the feed or water. Since the inclosed clipping appeared in two papers, read generally through this section, the *Philadelphia Record* and *Doylestown Intelligencer*, a great many think that my silo caused the death of my horses. My silage is taken into the entry about twenty feet from the nearest horses, but none of it fed to them, although two cows, kept in the horse stable, were fed on it. I cannot see how it could effect them, for there is none of this deadly gas spoken of, in my silo, but a sweet pleasant smell that men like. The feed and hay I have fed appears to be as sweet and clean as it could be, and the horses were watered

BUY THE BEST.

If you want the best low down wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned whiteoak. The front and rear

hounds are made from the best angle steel, which is neater, stronger and in every way better than wood. Well painted in red and varnished. Extra length of reach and extra long standards supplied without additional cost when requested. This wagon is guaranteed to carry 4000 lbs. anywhere. Write the Electric Wheel Co., Box 130 Quincy, Illinois., for their new catalogue which fully describes this wagon, their famous Electric Wheels and Electric Feed Cookers.

SEED TIME

is going to be late this season. Cold, frosty weather has held on longer than usual and when the proper time comes it will be necessary to get seeds into the ground in a hurry.

The "PLANET JR"

Seed Drill will be found the fastest and most effective.

Drills all kinds of garden seeds evenly and perfectly. The entire line of "Planet Jr" goods—**Hand Drills, Wheel Hoes and Horse Hoes** are unequaled in material and quality of work. Don't buy until you get our new catalog—free.

S. L. ALLEN & CO., Box 1107 D, Philadelphia.

Golden's White Wonder

Will remove grease spots, milk stains or dirt from clothing, where everything else has failed. Receipt and full directions for making and using this Great Chemical Discover. for **25c** This is absolutely indispensable in every household. Send to-d y, you will never regret it Address J.C. GOLDEN, Martin, Tenn.

$17.50

5 TONS...

We guarantee this harness to haul 5 tons **and no break.** Made of extra heavy **Oak Tanned** leather. **Traces** 3 ply. 1½ in. wide, 6 feet long. **Pads** heavy, well stuffed, with hook and terrets. Pole and breast straps 1¾ in. **Lines** 18 ft. long. Equal to any harness retailed for $26.

Our Price with two hitch straps **$17.50.** All kinds of Farm, Light Double and Single Harnesses. **82 styles to select from.** Shipped subject to examination without any money with order, to **be returned at our expense if not satisfactory.** Also Buggies, Phaetons, Surries, Spring Wagons, Speeding and Breaking Carts. **DON'T BUY** until you see our 164-page **Harness and Vehicle Catalogue.** Write us for it now. **We will save you money.**

Marvin Smith Co. 55-57-59 N. Jefferson St. HD 18, Chicago.

BABCOCK

Milk Testers.

Geared machines. Whirling parts nicely encased. Guaranteed accurate. Plain directions. Anyone can use successfully. Four bottle size $4. 8 bottle $5.50. Sent by freight or by express as ordered. **J. J. ANGUS, Plymouth, Wis.**

Parted In A Dream—(New) Pronounced by critics a beautiful song. Very popular. Founded on strange incident of Cuban war. Regular price, 50c. Sent to our readers for 25 cts., post-paid, including also miniature page of DARLING LENORE and MOTHER'S DARLING YET.

Darling Lenore—(New) Is called a very catchy, pretty song with beautiful flowing melody, all in waltz time. Becoming very popular. Regular price 50 cts. Sent post-paid to our readers for 25 cts. with a miniature page of PARTED IN A DREAM and MOTHER'S DARLING YET.

Mother's Darling Yet—(New) Pronouuced very pretty. Is extremely popular with singers of lullaby songs. Regular price 50 cts. Sent post-paid for 25 cts. and with it a miniature page of PARTED IN A DREAM and DARLING LENORE.

For 2 cts. I will send one miniature page of each of the three songs. Address the author,

HALBERT L. HOARD, Fort Atkinson, Wis.

PLOWING MADE EASY

MORRISON MFG. CO.—*Gentlemen:* I will say that I have used your **HEEL PLATE** for controlling the running of the walking plow and I find that it has a good many advantages. It will keep a plow running level. If my plow wings over one way or the other, I can fix it in three minutes so it will run alone. It will also keep the plow share sharp a considerable length of time. It is a very simple improvement and is all you claim for it.

Yours truly, FRANK WENKE.

A postal card will bring a **Beautiful Illustrated Catalogue Free.**

Address, **MORRISON MFG. CO., Ft. Madison, Iowa.**

at the spring where the family supply has been obtained for the last 100 years, I know. If you could throw any light on this subject, I am sure it would interest many dairymen in the east, as the disease is quite common, and fatal, nearly always. W. A. T.

Wycombe, Pa.

ANSWER.

It is hardly possible to conceive of a more vapid or shallow reason to be assigned for spinal meningitis, than the one you say the veterinarians give in charging it to the use of ensilage.

The veterinary profession is "cussed" with a lot of addle pated quacks, without education, ability, observation or reading, who jump at any baited hook as a conclusion, that is flung to them.

Spinal meningitis in men and animals is a very deadly disease. The cause of it has baffled the most learned investigators, although there seems to be some evidence accumulating, which would indicate that it is of germ origin. It quite generally appears in an epidemic form. W. D. H.

LOSS OF MILK FROM SORE TEATS.

I am having trouble with my cows' udders. The trouble starts in the end of the teat and goes on up in the udder, then the flow dries up, and she is no good after that. I have given salts and ginger every three days and spirits of niter every day, and never cured one yet. G. R. K.

Balto Co., Md.

ANSWER.

I really can't understand the cause of your trouble with the cow's teats, but I have strong suspicions it is the result of milking by some hard squeezing, hard jerking milking.

TREATMENT FOR COW POX.

I don't get good results from the use of your cow pox remedy. It don't seem to do my cows any good. If you have any other remedy, please give it to me. M. B. P.

ANSWER.

Safety, easy milk tubes are to be used in all cases of sore teats. Here is where you fail to cure, I presume, by this hand milking. I don't know of any better treatment for cow pox. You are to blame somewhere, I believe.

INVERSION OF THE WOMB.

I have a cow that dropped her calf the 17th day of February last. Since then, when lying down, her womb will protrude a little, also when she passes water and dungs. It has never come out as I have seen it in some cases. E. P.

Middlebow, Mass.

ANSWER.

Inversion of the womb is always a bad condition. Recurrence is a rule. This always requires extra care and attention. Let her lie in position, slightly inclining forward, so that there will be much less pressure behind.

A compress of any kind of old soft rags will do. Soak this in Bromo Chloralum, one to eight of cold water. Soak and replace twice a day; leave a small opening at the bottom to allow the passage of urine.

FAILURE TO BREED.

I had a heifer drop her second calf the first of December, '98, and has not come in heat since. She looks well and gives a good mess of milk. G. T. K.

Vt.

ANSWER.

Read the ads. in the DAIRYMAN. They are the best, cheapest and most reliable, and easily given. Select for yourself.

SORE TEATS.

I have a Jersey cow that has sore teats. A small scab came on one of her teats, and spread over one-half of it. Two of her other teats, also, have scabs on them now; they seem very painful. G. S.

Charter Oak, Iowa.

ANSWER.

Always use a milk tube of the correct pattern, when the teats become sore, and give a full dose of physic to each cow. Dress the scabs with spermaceti and almond oil, half and half, and one dram to the ounce, of pulverized gum myrrh to be mixed with this. Always stop hand milking just as soon as the soreness appears.

FAILURE TO WORK IN TREAD POWER.

I bought a one horse tread power for which I use a bull to run it. I have very much trouble to make this bull run that power, for as soon as I lead him on the lag, which is even or smooth, he will slip, which makes it impossible for him to run it. I tried to prevent this slipping by nailing on some cleats, but had to take these off again on account of him hurting his hoofs. F. G.

Debri, Mich.

ANSWER.

Don't know what to say to you. If the bull can't work the tread power without slipping or hurting his feet by the cleats, fix some sort of soft material over the cleats, or protect his feet.

Cow flatus pipe and probing should read, a six foot section—not a six inch section, as printed last week,—of garden hose, of good quality.

FEEDING SULPHUR TO COWS.

What effect has sulphur on cows? Would you advise feeding it, what proportion, how often? MRS. WM. MCC.

Helena, Ark.

ANSWER.

Sulphur is one of the very best drugs for many diseases. It is, also, one of the most dangerous to trifle with, at all times, but especially during damp, cold weather. It will kill all lice of every kind, and not do harm if carefully and knowingly given; but there are safer drugs for all the diseases, for which it is good. It opens every pore of the body, and permeates all and everything, even to the nails upon the fingers and toes.

RETENTION OF AFTERBIRTH.

I have a cow that has failed to clean herself of part of the afterbirth. She calved last Wednesday, and I think the calf came about a week to soon. T. B. B.

Oakhurst, Ga.

ANSWER.

Get an experienced person to remove the remaining portion. There is no medicine likely to be of any use. The best is one ounce dose of fluid extract of cotton root, until she begins to strain, then is the time to help her, pulling at each strain upon the end of the placenta which is found. One ounce first, in two hours another ounce, in three hours one or more, then stop; give no more.

PAPULOUS TUMORS.—EATING WILD PARSNIPS.

I have a yearling heifer whose belly and teats are covered with warts, not the dry seedy warts so common on cow's teats, but large soft fleshy excresences, which bleed freely on being excised; the animal is in excellent health and condition. I have also got a cow which acts strangely; from being one of the liveliest foragers agoing, then suddenly becomes dull and shiftless and loses her appetite; her eyes generally bright and full of life become dull and heavy; occasionally acts as though in pain, throwing up her head and shaking it vigorously; gets up and lies down, and is generally uneasy; while she does eat some, it seems to be only under compulsion; her milk will dry up for a few days, or nearly so, and then as suddenly return to her normal condition. Would eating the leaves of wild parsnips cause this?

Templeton Ore. O. B

ANSWER.

1. I don't believe the cow to be troubled with warts, they are papulous tumors. Paint them over with strong tincture of iodine, only a few at a treatment, and 70 grains of iodide of potassa for 10 to 30 days.

2. Yes, wild parsnips is the cause. They are a deadly poison to all warm blooded mammals; the papers are continuously reporting deaths of children, cows, etc., from eating wild parsnips. Immediate full dose of physic and repeat in five days with a smaller dose, in six after, a third dose.

PROBABLY BOT FLIES.

Have a Jersey heifer four years old; she is with calf about five months; about three weeks ago, when brushing her, I felt some small pimples, like elevations of the skin, which commence near the spine, and spread down about 5 inches on each side. They have grown to the size of an English walnut since then. There are about 25 or 30 of them on each side of spine. It irritates the cow, when I touch them, but there is no change in her milk production as to quantity.

Rhode Island. C G. M.

ANSWER.

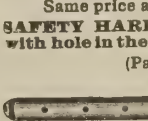
The situation is just where the bovine bot fly punctures and deposits its ova. If so, squeeze out the grubs. If not, these, then don't know exactly what form of tumors you may have. Cut off the hair close, and paint them over with *strong* tincture of iodine, a saturated tincture. You can quite easily find out if there are grubs inside the tumors by a close examination.

SMUT POISONING.

My cows seem to get stiff and tender on their feet. I have three or four that way now, but one of them lost all use of hind quarters; I applied blister to her spine and gave nux vomica and she got better again, but got a relapse and is now totally unable to move, and has lost her appetite and looks very poor. The local veterinary surgeon says the trouble is caused by a very small insect in the top of fodder, but I have fed a great deal of fodder every winter and never had any trouble before. R. H.

Carlyle, Ill.

ANSWER.



I suppose your veterinary surgeon alludes to smut. I think he was right, the symptoms indicate smut poisoning. You had better let your veterinary surgeon attend to the cows, as the disease is bad to manage, always; it is of a deadly nature. You have largely over fed and that may have something to do with conditions named. Other winters have nothing to do with the present, by any means. A thorough physicking will be good. Put one dram of nux vomica in the full dose of physic for a full grown and full sized cow.

THE LAWRENCE-WILLIAMS CO., Cleveland O.

What Shall We Do?

ED. HOARD'S DAIRYMAN:—I am one of you twenty-five cent subscribers, but you can count on me for a dollar as soon as my time expires. I can see you paper is just what a man needs who wants to make cows profitable. But I am a little puzzled as to what to do. I am a patron of a creamery and have sixteen cows, and they are dual-purpose cows, like all of my neighbors'. We get from the creamery about $22 a year per cow, and until I commenced reading HOARD' DAIRYMAN I had supposed we were making some profit. I now see that when feed and labor is taken into account, I have been working for my cows at a loss.

I also see that there are dairymen who write for your paper who make double and some of them three times what I do from their cows in clean profit. I am not satisfied with this general purpose talk. My wife says, "HOARD'S DAIRYMAN is right," and she asks, "If you are going to keep cows, work for cows, and take their milk to the creamery, why not have cows that will bring a good profit?" But then, she is always asking uncomfortable questions of me. I think the woman is right, however. Now, what course would you advise me to follow to put myself in a different situation where I can get a fair profit from my cows. Yours thankfully. E. C. W.

DuPage Co., Ill.

Our friend is where a great host of farmers are, who have gone into the business of dairying. They have become patrons of a creamery, and now they find that they must be to the same expense in every particular with cows that yield only $22 a year, that other men incur who have cows that yield $50. As in his case, until a ray of economic light shines in, from their reading a paper that discusses such questions, they supposed they were doing well, and yet, somehow, their pocket-book keeps telling them all the time that they were wrong.

Our friend asks, "What shall we do to get out of this situation?

If he expects to continue as a patron to the creamery and wants to get the best reward for his labor, we would advise him to take the following steps:

The first thing is to find out about your herd, so you can weed out the unprofitable ones and make no mistakes, and to do this you should know by day and by month just what each cow is doing. It takes but little time to do this and the knowledge is worth a great deal. So we say:

(1) Get a good spring balance that will record down to tenths and weigh twenty-five pounds. Take a sheet of stiff manilla paper, say nine inches wide and a foot long, and rule it off in the following manner, to represent thirty-one days. Have a sheet for each month:

March.	*Morning.*	*Evening.*	*Remarks.*
1			
2			
3			
4			

Tack up in the stable behind each cow a sheet of this ruled paper. When you milk a cow, hang the pail on the spring balance, get the net weight of milk and set it down in the place ruled for morning or evening for the appropriate day.

We can furnish these sheets ready printed from this office at trifling cost, if desired.

(2) Select a registered bull one year old from some one of the following breeds: Guernsey, Jersey, Holstein or Ayrshire. Select as good an animal, with a long line of well performing mothers behind him, as you can. Don't haggle over a few dollars in the price. You need a bull with strong dairy potencies in him, and such a bull is worth good money to you or any other man. Breed him to your best cows. Save his heifers and bring them up rightly, feeding them on skim milk, bran and oats, in such a way as to develop the dairy quality and keep down the beef tendency. When these heifers are fifteen months old, breed them to their own sire. They will calve when two years old. The resulting heifers, as you will see, will have the blood of the sire in double quantity in them. Keep the old sire to breed to his daughters as long as you can, but breed the granddaughters outside to a sire, if possible, of the same family as the first sire—a first, second or third cousin, say.

This will give you a herd of cows in a few years that will have merit and profit, provided that all the time you keep weeding out the unprofitable ones.

When you have a chance to buy a likely young grade cow of the same breed as your sire, do so.

Proceed on the principle that it is better for your pocket-book to have five good cows alone, than five good ones with five more poor ones to eat up all the first five can produce.

In the mean time strive to read and improve your mind and judgment on all sides of this dairy question—the breeding side; the feeding side; the stabling and handling side; the care of the milk; the growing of crops fit for dairy food, and many other sides.

On all these sides, any farmer needs access to the best dairy reading in books and papers he can get, for it is a big question.

Thousands have followed out the steps we have noted and have brought their herds of cows up from 150 lbs. to over 300 pounds per cow. The price of butter cannot get so low that they will not make some profit, whereas with their former cows, former ideas and former practices, all on the same dual-purpose, not dairy-purpose grade, high prices for butter rarely brought them any profit.

Avoiding Bitter Cream.

How shall we keep cream from getting bitter in winter? Mainly by preventing its suffering from the effects of the prevailing low temperature. Milk or cream does not get bitter when it is maturing naturally at a proper temperature. Butter with a bitter flavor, coming from small home producers is of frequent occurrence. It is usually from farms where the house-wife with poor facilities but good dairy instincts refrains from setting her milk in the hot kitchen pantry and puts it in a room far too cold for it. In the latter place, where the temperature is usually a little above freezing, the milk will remain sweet for several days, tardily casting up its cream, and then without any acidity developing, a fermentative change takes place resulting in the characteristic bitter flavor.

The natural end of healthy milk is to get sour in at the most from two to three days. Before the limit of that time in from 24 to 36 hours, and while the milk is perfectly sweet, the butter fat should all be extracted therefrom and stored in a separate vessel to mature. I think it better that the ripened cream be churned in 12 hours after skimming, or at least in 18 hours at the longest. I mean by this that the cream should be kept at a warm enough temperature to ripen within that period, so as to be fitted for churning. To avoid any bitter fermentation during cold weather, milk should be set for creaming in an apartment having a uniform temperature of 50 degrees. Then, the milk being skimmed within 24 or 36 hours, the cream should be matured at 65 degrees.

Avoid the hot kitchen pantry with its mixed odors of cookery on one hand and a cold room on the other. The atmosphere of the dairy room must be pure as well as of a mild, equable temperature, or foreign flavors will displace the natural one in the butter. The house-wife who wishes to make a few pounds of butter per week throughout the winter and can find a ready sale for it at a maximum price should carefully observe the above principles. Another thing: Most small winter butter makers do not color their product uniformly. The average consumer, although he is fully aware that the butter he is eating is artificially colored, likes to see it of a natural hue. It really tastes better to have it so, which proves how much the eye acts as a guide to the palate The worst mistake is in coloring the butter too highly, which is almost as bad as not coloring it enough. A happy medium is in striking a shade of the natural color of the June product. With small makers this compels the greatest accuracy in measurement, and the employment of a perfectly reliable brand of butter color.—*American Agriculturist.*

THE NEW METHOD OF BLOOD PURIFYING.

What the New Discovery in Medical Science Has Accomplished.

The Prompt Way to Cure Yourself When Symptoms Show That Your Blood is Out of Order.

THE EMINENT SPECIALIST'S FREE OFFER TO ALL READERS OF "HOARD'S DAIRYMAN."

For a great many years it has been the custom for sick people to say: "My blood is out of order. It needs purifying. I feel all used up. My skin needs clearing. My brain feels tired."

They are right but do they act right?

They generally go and get a laxative (bowel-cleaner) to purify their blood.

Does their blood run through their bowels?

Science has to-day furnished proofs that all the purifying that your blood needs, in fact, all that can be done must be done by your kidneys.

All the blood in your body passes through your kidneys once every three minutes.

The kidneys strain or filter out the impurities in the blood—that is their work.

Purifying your blood is not a question of taking a laxative or physic.

Does your blood run through your bowels?

What the bowel-cleaner does is to throw out the poisons confined in your bowels ready for absorption into your blood, but the poisons which are already in your blood, causing your present sickness it leaves there.

There is no other way of purifying your blood except by means of your kidneys.

That is why bowel-cleaners fail to do their work—they fail to help the kidneys.

When you are sick then, no matter what you think the name of your disease is, the first thing you should do is to afford aid to your kidneys by using Dr. Kilmer's Swamp-Root, the great Kidney Remedy.

In taking Swamp Root you afford natural help to nature, for Swamp-Root is the most perfect healer and gentle aid to the kidneys that is known to medical science.

Dr. Kilmer, the eminent physician and specialist, has attained a far-famed reputation through the discovery and marvelous success of Swamp-Root in purifying the blood, and thereby curing chronic and dangerous diseases, caused by sick kidneys, of which some of the symptoms are given below.

Pain or dull ache in the back or head, rheumatism, neuralgia, nervousness, dizziness, irregular heart, sleeplessness, sallow complexion, pimples, blotches, skin troubles, dropsy, irritability, loss of ambit on, obliged to pass water often during the day, and to get up many times at night, and all forms of kidney, bladder and uric acid troubles.

Swamp-Root is sold by all dealers in fifty-cent or one dollar bottles. Make a note of the name, SWAMP-ROOT, Dr. Kilmer's Swamp-Root, and remember it is prepared only by Dr. Kilmer & Co., Binghampton, N. Y.

The great discovery Swamp-Root has been tested in so many ways, in hospital work, in private practice, among the helpless too poor to purchase relief, and has proved so successful in every case that a special arrangement has been made by which all readers of HOARD'S DAIRYMAN, who have not already tried it, may have a sample bottle sent absolutely free by mail, post-paid. Also a book telling more about Swamp-Root and containing some of the thousands upon thousands of testimonial letters received from men and women who owe their good health, in fact, their very lives, to the wonderful curative properties of Swamp-Root. Be sure and mention HOARD'S DAIRYMAN when sending your address to Dr. Kilmer & Co, Binghampton, N. Y.

THE NEW BOOK
Feeds and Feeding

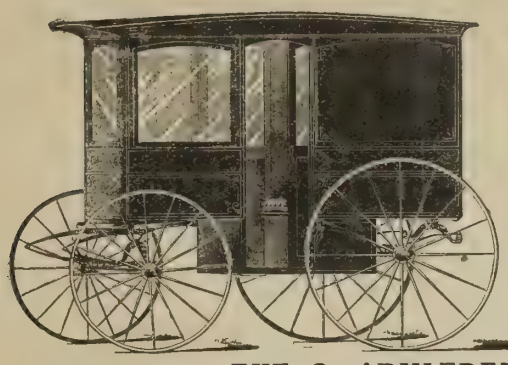
By Prof. W. A. HENRY.
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premum.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.



Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehenisve from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

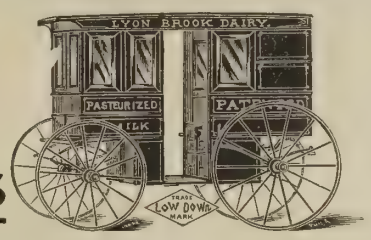
This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

We make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.



Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

There Are Others

But they all came after ours.

WE ARE THE ORIGINATORS

Of the now famous "LOW-DOWN" Milk Wagon.

Imitation is an acknowledgement of real merit. Thirteen years' trial has proven the Parsons "Low-Down" Wagons to be **THE BEST.** ☞ Secure our catalogue of strictly first-class, hand made, up-to-date, durable work.

PARSONS' "LOW-DOWN" WAGON WORKS,

EARLVILLE, N. Y.

Don't Pay Three Profits

No. 3034 Buggy. Price $37.25 With Leather Quarter Top.

If you are going to pay for a carriage why not pay the least you can for the best vehicle? Get all you can in material and workmanship—pay as little as you can for handling and "extras."

You save the jobber's commission and the retailer's profit when you buy direct from the factory. You pay the cost of making with one moderate profit added. We are not agents, but manufacturers of buggies, carriages, surreys, phaetons, wagons, harness and horse accessories. Everything guaranteed. With our illustrated catalogue you can order easily and safely. If what you order does not suit, send it back and we will pay the freight both ways. First, get the catalogue. You are welcome to a copy.

THE COLUMBUS CARRIAGE & HARNESS COMPANY, COLUMBUS, O.

DID YOU

Ever walk behind a plow all day and toward evening experience that soreness of arm and shoulder because you had a plow that persisted in winging over? If you want to know what will cure **the plow,** drop us a postal card. The heel plate will do it; it weighs but 8 ounces, but it's a wonder worker.

MORRISON MFG. CO., Ft. Madison, Iowa.

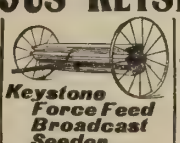
Be Fair with Your Fields

and they will be fair with you..... Listen a moment.

Every time you take a crop off a field you relieve it of just so much fertility. You should do something to restore that fertility. Barn yard manure is the best fertility restorative known if properly handled and properly applied. Even a small amount can be made to go a long way and accomplish great good if finely and evenly spread. This cannot be successfully done by hand—it is work for a perfected machine. The only machine known which accomplishes this is

The KEMP MANURE SPREADER.

It will Double and Treble the Value of the Manure Heap.



It spreads all kinds of **fine and coarse manure evenly;** it makes no "skips;" does not dump a great load in one spot, but covers the entire ground evenly. Tears up coarse and lumpy manure and makes it fine. Better than anybody can do it by hand. **Spreads lime, wood ashes, salt, etc.,** equally well. With the drill attachment **it puts the manure direct into the open drill.** Made in three convenient sizes. Ask the opinion of anybody that uses one. **Write for illustrated catalogue.**

Kemp & Burpee Mfg. Co., Box 46, Syracuse, N. Y.

THE FAMOUS KEYSTONE LINE OF SEEDING, PLANTING AND CULTIVATING TOOLS.

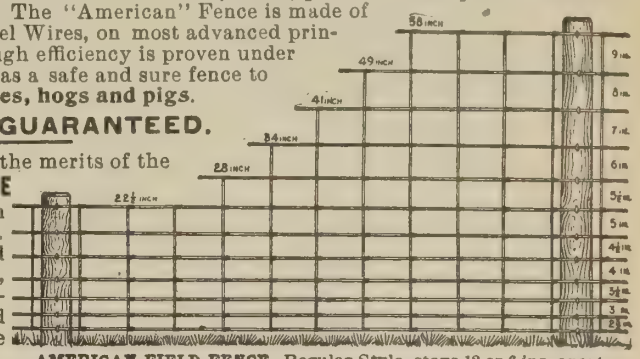
Victor Disc Harrow —greatly improved for '99. Oil tubes to the bearings from top of frame—positively exclude all dust or dirt. Steel scrapers, double adjustment levers—easy to place gangs at any angle. Ball bearing—no side pressure and easy draft. Made 4, 5, 6, 7 and 8 ft. wide, with 18 or 20 in. discs. SEEDER ATTACHMENTS are made for 6, 7 and 8 ft. disc harrows.

Keystone Force Feed Broadcast Seeder are made 8½ or 11 ft. wide. Sows broadcast all small grains in any quantity in the best possible manner. Mounted on low steel wheels. Made with or without grass seed attachment. Equipped with CULTIVATOR ATTACHMENT if ordered. Made with and wheels or middle wheels. Has the best force feed we know. Send for special Seed Circulars.

Keystone Rotary Drop Corn Planter —it's a whole hill drop, each hole in seed plate holds enough grain for a hill. It never skips or misses. Equipped with Automatic Wire Reel. Has a drill attachment. Gear throws out automatically at end of row. Always drops at even depth because of the shoe gage on each runner.

Keystone Potato Planter —sprung quickly into popular favor because it is a simple and effective machine for the purpose at a reasonable price. Fits the needs of the man who grows an acre or two of potatoes, but who is not regularly in the business. Plants 10, 14, 17 or 20 inches apart in rows. Send for circulars.

Keystone Walking Cultivator. This is clearly a leader among the machines of its class. It is made entirely of steel and iron except tongue, singletrees and neck yoke. Strong and well braced in every way. Steel braces and four soft center steel shovels. Full line of Riding Cultivators also. Send for circulars.



KEYSTONE MANUFACTURING CO., 39 RIVER STREET, STERLING, ILLINOIS.

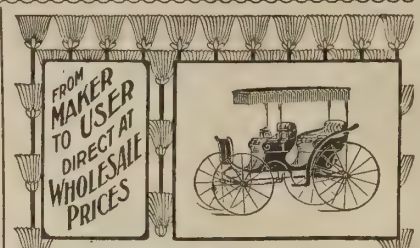
HAPGOOD PLOW CO., Box 196, Alton, Ill.

Only Plow factory in the United States selling direct to farmer.

Water in the Stable a Necessity.



It is now regarded as a necessity that stock in the stable should have constant access to water of suitable temperature. The dairyman who to-day turns out his cows to drink, is as far behind the age as the farmer who cuts his grass with a scythe, or rakes it up with a hand rake. Write for descriptive catalogue of the best known and best System of watering Devices for Cattle in Stables, to

C. E. BUCKLEY & CO., Poughkeepsie, N. Y.

Absolutely perfect. Soon pays the cost. Cheapest because best.

Water always fresh. No disease where used. Send for catalogue.

STANLEY'S CORRUGATED STEEL HINGES

are not like other hinges; they are better. Why? Well, because they are corrugated, which is just like so much re-inforcing; makes them at least 50% stronger, just as angle steel is stronger than flat steel. Are so made they can't bind on the pin even if hinge gets rusty. Are ornamental too. Don't be satisfied till you know all about them. Ask your dealer or send to us for circulars, &c.

THE STANLEY WORKS, Box 12, NEW BRITAIN, CONN.

THE SHARPLES TUBULAR CREAM SEPARATOR.

"The bowl alone revolves."
"It spins on air."
"It is a hollow bowl."

No rubber rings. Clean skimming.
No metal bearings. Fast skimming.
No spindles. Superb cream.

When asked to do so, we gladly place these Tubular machines with the most exacting buyers or with the users of any other make of separator in existence, and guarantee superior results in clean skimming and in the quality of the product.

A Tubular separator will in almost every case increase the yield of butter in a creamery over and above the best that can be done by separators of other manufactures which may be in use, sufficient to pay a heavy percentage on the whole cost of the machine.

No. 25 Tubular, warranted capacity 2,500 lbs. per hour.
No. 40 " " " 4,000 " " "
No. 60 " " " 6,000 " " "

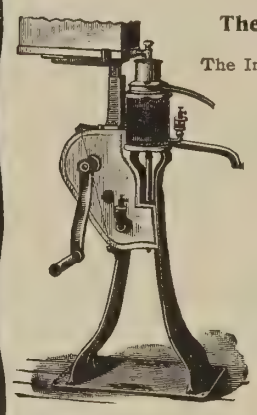
FACTS, NOT FICTION,

ABOUT



The Improved U. S. Triple Current Separators

They are the cleanest Skimmers on the market, as witness the reports from the State Experiment Stations and users the country over. They are also noted for their simplicity, ease of operation and durability.

A Few 1899 Experiment Station Reports.

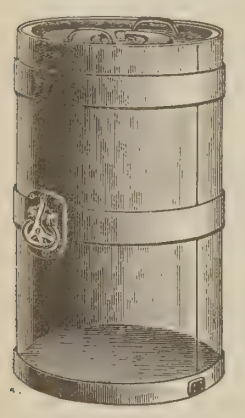
Massachusetts,	average of 19 tests,	January 7th	to 31st,	.033 of 1%
Ohio,	" 19 "	" 10th	to 21st,	.034 of 1%
Vermont,	" 18 "	" 9th	to Feb. 3d,	.038 of 1%
Wisconsin,	" 17 "	" 2d	to 19th,	.03 of 1%

An average from 73 tests of skim milk of .034 of 1%

The U. S. Excels in Every Particular

FORESTVILLE, CONN., Feb. 18th, 1899.
The Improved U. S. Separator is giving excellent satisfaction. In comparing it with other makes, have found it to far excel in every particular—in thoroughness of skimming, ease of operation, design and finish, simplicity of construction, therefore easy to clean, and durability. Any one contemplating buying a Separator should investigate the merits of the Improved U. S.
WILLIAM F. KENNEY,
Buttermaker for J. Hart Welch.

The U. S. the Best on the Market



DEER PARK, MO., Feb. 25th, 1899.
The butter I exhibited at the St. Louis Fair scored 98½ points and won the Sweepstakes over the creamery butter from several of the best Creameries in the United States. It was made from cream separated by the No. 5 Improved U. S. Separator I have been using for nearly three years, which has always been in running order and given entire satisfaction. If I had to buy another it would be an Improved U. S., for I think it the best on the market.
NATHAN KING.

No Loss of Cream in the Skim Milk

BROMPTON FALLS, P. Q., Jan. 31st, 1899.
The No. 1 and No. 0 Improved U. S. Separators purchased last spring are giving perfect satisfaction. They run smoothly and easily and take all the cream out of the milk. They are simple, durable, and not liable to get out of order.
A. MARTEL & CO.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

WORTH $100.

Here is what a leading dairyman, one of the proprietors of the Minerva creamery, at Minerva, Ohio, thinks of the Storrs College report, we published a short time since:

ED. HOARD'S DAIRYMAN:—I consider the tables in your paper of March 24th in regard to the Storrs College herd worth $100, or more, to every farmer. It is just what I have wanted to find out. I wish every farmer in the country would study it all, and then act. It will be worth thousands of dollars to them every year. F. E. BOOTH.

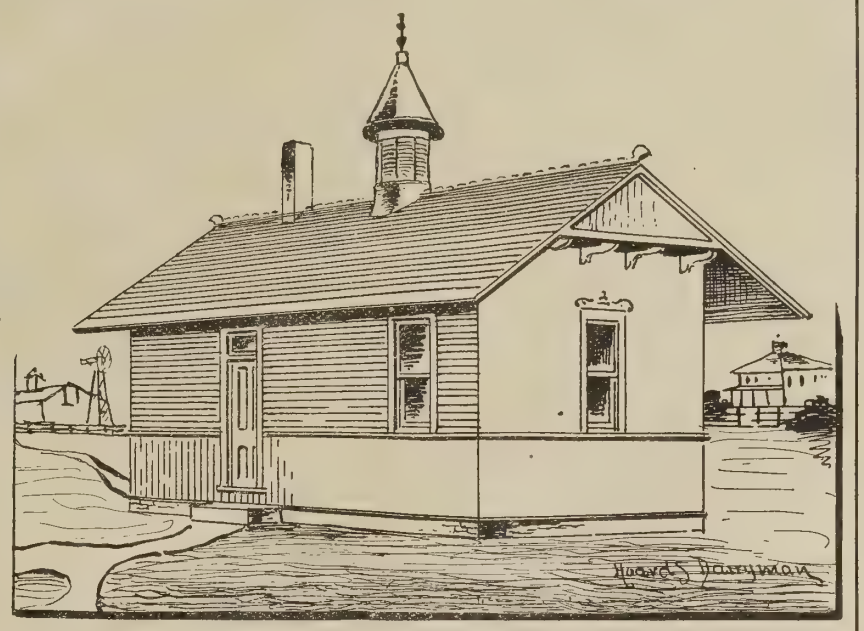
Minerva. Ohio.

EMBALMING MILK.

"Freezene."

Running a close second to the borax compounds as a milk preservative is "freezene". Letters which we receive indicate that it is being widely advertised throughout the country, and its use is pressed on the dairyman at every opportunity. The name is a stroke of genius; it makes one think of ice, refrigeration and cold, but the properties of the article hardly follow its name.

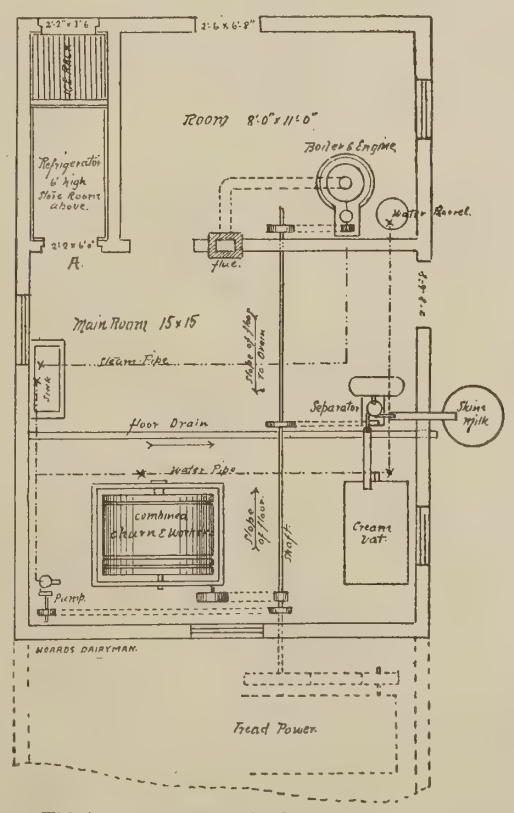
Freezene is manufactured from wood alcohol; its chemical name is formic-aldehyde.



It is a gas, soluble in water to form a 40% solution. It possesses the property of forming a compound with gelatin and rendering it insoluble. In the same way it kills the bacteria and spores by uniting with the material of which they are composed and thus preventing their growth. It is a powerful poison to all animal and vegetable life. When applied to the skin it destroys its life and causes it to be thrown off as dead matter. Even in dilute solutions it has this effect if applied to a delicate skin. It is a thorough and efficient destroyer of life in all and every shape. A small amount of this chemical, when added to milk, will keep it from souring for a number of days, even in warm weather. It acts by killing the bacteria and thus preventing the formation of lactic acid.

The question is: How much of the above chemical compound does a man want to take into his stomach and how much of the claims for the innocence of this compound can be believed?

Can a substance be a powerful poison outside of the body and an innocent compound in the stomach, when it is used in sufficient quantities to destroy a life principle, so tenacious of life as bacteria cells? Can a compound kill the skin on the hand when used in dilute solutions, and cause it to peel off as a dead layer, and yet have no effect on the delicate mucous membrane of the stomach? We doubt it; and we also doubt the testimonials of doctors and professors, who laud it as a perfectly innocent, innocuous poison; one that will kill the weeds and spare the grain, sure death to bacteria, but harmless to children.



A FARM CREAMERY.

In response to recent requests for plans for building a farm creamery, we reproduce here cuts and description published in February, 1897, nothing better adapted to the purpose having come under our observation since that time.

It is not to be expected that any one plan, in all its details as to size and arrangement, will be equally acceptable to every intending builder. These, however, can easily be modified to correspond with personal preferences.

The main points in the accompanying plan are a workroom (15×15) A, containing all the machinery and supplied with cold and hot water pipes, drains and shafting. In the rear, and separated from this by a substantial partition, is the power room and place for cold storage. This provides for all that is indispensible.

Our original description and comments were as follows:

The main building is 16×24 feet, outside dimensions, and the cut shows wide projecting eaves in order to protect the sides from the excessive heat of the sun in summer. We think this feature of the plan worthy of attentive consideration. The extra cost will be inconsiderable and the resulting benefit quite perceptible.

The ground plan is fully self explanatory. The draughtsman has specified one of the combined churns and butter workers as this is the "latest" demand for our progressive butter makers. It is by no means indispensible, and separate machines for these purposes may be substituted.

In the matter of construction, regard should be had to keeping out the cold in winter and heat in summer. To this end it is well to provide, at least, two dead air spaces, and every mechanic, worthy of the name, knows how to do this by using building paper. This may be done without increasing the thickness of the walls, but we should prefer to curtail the inside dimensions somewhat and make the outside walls ten inches instead of six.

We believe it better to have a separate building for an ice house. These structures go to decay very rapidly and are never quite free from filth.

Build a fireplace at the bottom of the flue, opening into the main room and also leave an opening near the ceiling to which fit a register, that may be opened or closed at pleasure. This will, in a measure, obviate the necessity for building the cupola. The latter, however, adds to the symmetry of the building, and if connected with the room below by a flue leading to it, will not be wholly unservicable.

DEGENERATION OF DAIRY INTELLIGENCE.

What is it in this dairy business that seems to act like a demoralizer of the minds and judgment of the farmers in the older dairy districts? To illustrate: Go into the old cheese making districts of New York and Ohio, where they have made cheese for forty years, and it will be found that the farms have declined in fertility until they will produce but little, if any, more than half the cow food they did when dairying was commenced. Another: Let a cheese factory be started in any community and it will be found that for the first year or so it will take from one to three pounds less milk to make a pound of cheese than it does after the factory has been running several years. In other words, the farmers seem to progress towards poorer milk as well as poorer soil.

Another: Go into any of the old dairy districts in the west where there is a large cow population, and there seems to be less real disposition among many farmers to improve in knowledge, in their methods, in the quality of their cows, in the neatness and cleanliness of their stables and in all those things that make up real dairy progress, than was exhibited twenty years ago. There seems to grow into their thought and practice the idea that there is more profit for them in being less and less a dairyman in the best sense of the word.

There is a departure on the part of many from those sound doctrines of faith and practice that build up the business in the first place.

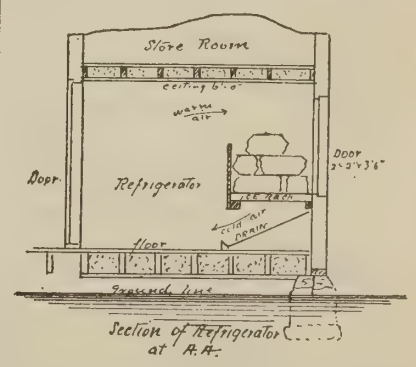
In his interesting letter on the "Dairy Outlook in Northern Wisconsin," on page 103 of this volume, Prof. Henry speaks of the way the farmers of Barnett county care for their cows, in the following significant manner:

"In this particular they are ahead of some other sections in the state that I visited, where, while more cows are kept, the farmers are more careless as to their care and management."

Three things exist which should nerve every dairy farmer up to "eternal vigilance" in mind and method.

1. The sure prospect that without it the farm will steadily decrease in fertility, just as it has in many older dairy sections. If we do not keep up the bank account we cannot draw from it in times of emergency.

2. If we do not keep our mind and purpose alive to the study of our business, our cows will naturally decrease in quality and in profit. We will cease to produce good cows, and depend on the haphazard, brainless breeding of others, who know even less about it, and who make it a matter of mere accident.



3. As we increase in cow population in any district, so do we increase the hazard of infectious diseases. So do we increase the danger of carelessness and indifference. When there were but few herds and few in a herd, abortion and other diseases were almost unknown in the west. How is it now?

This fact alone should teach the dairy farmer in such districts that he cannot afford to be indifferent to his own intelligence and the saving effects of good, progressive study and care in stable sanitation.

But we recur to the question asked at the head of this article: "What is it that makes so many farmers in the old dairy districts more indifferent to dairy progress than they were when they started in business?" Can they afford it in these times of low prices, when it is good thought, good sense, and the wisest of methods, only, that will bring a profit?

It is a Fraud.

We struck an anomaly the other day in Chicago. At the wholesale houses fine creamery butter could not be bought for less than 21 cents a pound. At the retail houses it was offered freely at 15 cents. There are two possible explanations for this. The butter offered at retail for 15 cents was bought just before a big rise. That is one. The other is that it is a lie and a fraud through and through. It was not creamery butter at all,

but decderized packing stock or butterine. But it looked all right. Choice dairy butter was also offered at the same price, but choice dairy butter sold at 19 cents wholesale at the same time, and the 12 cent dairy butter was also a fraud. But it did look fine! It was printed and stamped beautifully, colored to a lovely straw color, was in appearance above reproach, but it was a fraud. No wonder genuine butter is cheap, when compelled to sell in competition with lard, tallow and cottonseed oil compounds, as well as rank dairy butter with the stink chemically neutralized. E. C. BENNETT.

THE legislature of Vermont has enacted a law which requires that all operators of the Babcock test at creameries and cheese factories should have a certificate for competency in handling the test.

COLORADO, naturally a good dairy state, spends $150 a year for dairy teaching. In the 20th Annual Report of the State Board of Agriculture and the State Agricultural College, not a line is given to any record whatever of dairy work. How can such things be?

THE SHEBOYGAN DAIRY BOARD OF TRADE.

AT the annual meeting of the Sheboygan Dairy Board of Trade, held March 29th, A.D. De Land, a former president of the Wisconsin Dairymen's Association, was elected president; Henry Weaver, secretary; and Henry Blouke, treasurer. It was resolved to meet every Wednesday afternoon during the coming season.

THE proposed big milk trust of Philadelphia, has gone to pieces under the determined opposition of the small dealers, who united under the leadership of a plucky woman, to the number of 150. Everywhere can we see that all other classes, even the most ignorant laborers, can organize and unite for their mutual defense except the farmers. They will lie down and let the oleomargarine swindle and all kinds of frauds and monopolies ride rough shod over them. And if there are farmers in the state legislatures, they will stand up for the old fraud as many did in Kansas. It is very evident in these days of trust, monopolies and frauds of all kinds, that the average farmer needs a good deal of education as to the most common principles of self defense, self culture and self improvement.

A MILK EMBALMER.

The almost criminal greed for gain that would swindle the consumer with the counterfeit stock yards butter, on the plea, Judas like, that it is "for the poor," finds a natural outcome in the furnishing "embalmed beef" for our soldier boys, through the use of chemicals. Is there anything these men will stop at in their mad haste to pile millions of dollars on top of millions? The sentiment of the public is being aroused to the danger that exists when a departure is made in the preparation of food from natural sources and methods. When these oleo men can put paraffine and diseased fats, like the oil tried from dead horses, in their counterfeit butter, as has been proved, why should not the milkmen dope their milk with the deadly formaldehyde? One is no worse than the other and both are swindlers and law breakers of the worst type.

A TRIUMPH OF ORGANIZATION.

For two years a few public spirited men in New York have been trying to organize the milk producers of that and adjoining states into what was called the Five States Milk Producers Association. The object of the association was, by close organization, to force the milk dealers of New York city, who have formed a syndicate or trust, to pay a fair price for their milk.

The plan followed was to visit the different localities sending milk to the city, and have the farmers sign articles of agreement and give power of attorney to the committee chosen for that purpose, which articles gave the committee the power to make a contract with the syndicate for the sale of the milk of all members of the association for the term of three years.

The committee have finally secured the contract at three cents a quart for six months and two cents a quart for the balance of the year. This means an average of $1.17 per hundred for the year. At present the producers are receiving obout 80 cents a hundred pounds by the year, while their milk retails from 8 to 10 cents per quart.

This is a most notable instance of the value to farmers of fighting the devil with fire. One of the leading men in this work of organizing the milk producers has been Mr. Ira L Snell, of Kenwood, N. Y.

MICHIGAN CREAMERIES.

The Michigan creameries the past year, seem to have been very successful as business concerns.

The Martin Creamery company of Allegan county has made nearly 35,000 pounds of butter the past year, and paid a dividend of 10% to stock holders.

A 20% dividend has been declared by the Hillairds Creamery company of Allegan.

The Vermontville creamery has distributed over $13,000 the past year in that vicinity, 14% dividend.

At the annual meeting of the Beaver Dam Creamery company, Ottawa county, a dividend of 90% was declared.

Overisel Creamery, Ottawa county, 22%.

Dorr Creamery, Allegan county, paid patrons nearly $13,000 in 1898.

Drenthe, Ottawa county, 55%.

Grass Lake, Jackson county, 17%.

Freeport, Barry county, 13%.

Litchfield, Hillsdale county, 35%.

Jerome, Hillsdale county, 7%.

Kellogg, Allegan county, 7%.

Woodland, Barry county, 10%.

Twenty-four creameries show an average of 20% dividend.

Denmark, in order to preserve its export butter trade, has passed a law making it a misdemeanor to use salicylic acid, formaline, or any "preservative" of any kind, in milk or its products.

It Gave Him a Definition.

ED. HOARD'S DAIRYMAN:—I was talking with one of my patrons today. About three years ago I had hard work to get him to subscribe for the DAIRYMAN. Today he said:

"The DAIRYMAN has been worth hundreds of dollars to me and I expect will be worth hundreds more. For the first time in my life I began to get a square definition of things. Nowhere else in this land that I know can a man have the company of as many bright, successful dairymen as in the DAIRYMAN. Such men are worth a mint of money to any man who knows enough to know what he needs to know."

I thought I would send you this little tribute as a sort of encourager to you.

Keep right on fighting the poor cow, oleomargarine, ignorance and carelessness—the four devils that are roasting the life out of the dairy farmers of this country. Yours as ever. T. C. L.

Bremer Co., Iowa.

There are thousands of acres of abandoned farm lands in Indiana, according to the official declaration of its Governor. Wearing out farms is a bad thing, and the practice is working west. It will never pay us to spoil our farms in that way.—*E. C. Bennett.*

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids.*

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc, and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat.* Whether fat is actually digested and thus passed on into the circulatory system in a changed form, or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained, by some, that the fat in the milk comes, largely, from the crude fat in the food, but it has been demonstrated that it is not absolutely necessary for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS Protein	Carbohydrates.	Ether extract.
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

HOW OFTEN SHOULD COWS FRESHEN?

Will you kindly advise me through your valuable paper, how long a mature cow should be milked before being served? Upon inquiry among dairymen in this section, I find that the majority of them have their cows come in fresh about every eighteen or twenty months, and one party advised me every two years was often enough. I have not had much experience in this business, and would like to have the advice of your paper.

Norfolk, Va. W. G S.

Under ordinary circumstances, cows should freshen once a year. For special reasons the interval may be increased or decreased, and in exceptional cases, may be extended indefinitely.

COW PEAS FOR MISSOURI.

Will you please inform me which kind of feed to grow for milk cows for winter use of the following varieties: millet, cow peas and oats, (sowed together,) or sweet corn for fodder.

I am a new beginner in the milk business, and never did raise any kind of feed. I am breeding A. J. C. C. Jersey cattle.

If there is any one in this part of the country that ever raised cow peas, I cannot find him. Please tell me how to plant and what kind of peas that is sown with oats; if these will do well in this section, and about how many acres for nine cows. T. A. W.

Maryville, Mo.

It is never wise to put one's sole reliance upon a single crop of any kind. If we were living in Missouri, we should certainly raise some of these cow peas, and should try some without any other crop, and some with oats or sorghum or both. We should also raise corn and oats and try some alfalfa.

For directions as to the manner of raising the cow peas, varieties and amount of seed per acre, see page 158.

AS TO MANGERS AND FEED BOXES.

In the DAIRYMAN of March 31, 1899, page 129, in answer to W. P., Woodbine, N. J., you say "the writer of this reply discarded feeding boxes and mangers of every description years ago"

Will you please give us your method of feeding hay, grain and silage. We have had trouble with all the feed boxes we ever used, or rather with their corners.

Menominee Co., Mich. C.

The plan followed by the writer is to have a smooth, level floor in front of the row of cows, and the grain, silage, hay or other coarse fodder is simply placed on this floor, within convenient reach of each animal. Of course some of this is scattered and pushed out of reach, but it is a very small chore to go along in front with a broom and sweep it back into place. We are well aware of the standing objection, that without some sort of a partition, one cow may rob her neighbor, but our experience is that this occurs only to a very limited extent, if at all.

We have so far modified the above plan, in front of one row of cows, as to introduce a common V shaped continuous trough, in which to give the cows water, and the feed of all kinds is put before the cow, the same as when the trough was not there. We have the feeding floor raised somewhat above the platform on which the cows stand, and the edges of this trough are even with the floor. We like this arrangement very much.

WILL IT PAY TO FEED GRAIN IN CALIFORNIA?

Can I feed grain at the following prices per ton: Oil cake $32 50 per ton, cocoanut cake $25.00, middlings or shorts $21.00, bran $20.00, corn meal $24.50, rice meal $18.00? If I can, please give me a ration for grade Jerseys.

Present feed, pasture (Italian rye grass, 18 to 21 inches long, and white clover), some carrots and all the oat hay they will eat clean at night.

I send my milk to a creamery, average price 80 cents per hundred for 4 per cent milk.

Is it necessary to scald bran?

Cal. H. Mc C.

With pasture of the character indicated, we should feed little or no high priced grain. A pound or two each of the cocoanut meal and bran would not be amiss for cows that are at the height of productiveness.

Experience has shown in the few cases where it has been tried, that cows fed some dry forage when on pasture seem to do quite as well as when given grain.

It is not necessary to scald or wet bran for feeding. It is better to feed it dry, unless some special object is to be obtained.

TO KEEP UP THE FLOW OF MILK.

Will you please formulate for me a ration, if you can, out of corn and cob meal, bran, clover hay and cut fodder. Our ensilage will be gone in about a week, and we would like to keep up the flow of milk. The cows are most all Jerseys, some fresh last fall and some fresh now. J. F. McM.

Wilmington, Ohio.

We fear you have made a mistake in curtailing the daily allowance of silage so as not to make it hold out until you can turn the

TO MEN WHO PRODUCE MILK FOR CITY USE.

If there is a cow keeper on earth who needs the best information on the science of feeding cows, it is the city milk producer. Do you know that it is a demonstrated fact in hundreds of cases that HOARD'S DAIRYMAN has given advice that has reduced the cost of feeding from 25 to 50 per cent? This means just so much added to the revenue.

Don't throw this paper down with the idea that there is no science of feeding. Don't think that the scientific investigators are all wrong and you are all right.

"Verily, friends," as the Hoosier preacher said, "there's a heap to learn." HOARD'S DAIRYMAN devotes more effort and space to this feeding question than any other paper on earth. It will pay you to take the paper and look into it.

cows to pasture. When we come to the first of March and our silage is getting so low that it will not last, if the full allowance is given every day, we reduce the amount by a half or a fourth as may be necessary to make it hold out. It is, of course, too late now to remedy this mistake, if it was one, and therefore you must do as best you can. We suggest the following as the minimum daily allowance:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
15 lbs. clover hay.....	12.70	1 02	5.37	.26
6 lbs. corn stover.....	3.57	.10	1 94	.04
6 lbs. bran.....	5.29	.75	2.32	.18
4 lbs. corn and cob meal.....	4.45	.32	3.75	.18
Totals.....	25.96	2.19	12.79	.66

Very likely you may have difficulty in getting all the cows to eat the amount of roughage specified, but in any event we would not let down on the grain. If at all practicable to get some linseed oil meal, we would advise feeding at least a pound a day to each cow.

WINTER AND SPRING WHEAT BRAN.

Is there any difference in feeding value for cows, between spring wheat bran and winter wheat bran? I am feeding grade Jerseys for butter, and find your paper very valuable, but I cannot find anything pertaining to the above question. There is a difference in price here, and I wish to know which is better. A. H. B.

Pittsford, N. Y.

There is less difference in the average of all analyses of winter wheat bran and spring wheat bran, than there is between different samples of either. Such difference as there is in the averages, favors the spring wheat bran, but it is so trifling that it ought not to make any material difference in the price.

A MICHIGAN RATION.

Will you kindly formulate a ration for grade Jersey cattle with a few thoroughbreds? Rye bran, per ton, $15; rye middlings $15; buckwheat $13; linseed oil meal $25; timothy hay $10. We cannot get wheat bran very often, and are out of corn stover. We deliver the milk and cream in town from about thirty-five cows and want a large quantity of good rich milk.

Niles, Mich. C. W. H.

We expect the time will never come, in our day at least, when the greater number of dairymen will come to a thorough belief in the proposition that the feed given to the cow has no effect upon the quality of the milk, except as it may affect the flavor and color. Numerous experiments have been carefully conducted with the view to ascertain whether the per cent of fat in the milk could be changed by changing the feed. In some of these experiments, a very slight change has been noticed, but whether caused by the feed or other circumstances, is, of course, undetermined; but in the great majority of the experiments, there has been no perceptible change in the per cent of fat, either increasing or decreasing with the change in the feed. The quantity of milk may be greatly modified by the feed, increasing or de reasing as it increases or decreases, and thus the *total* amount of fat may be changed.

But we ought to say, in this connection, that sound feed tends to the production of sound milk, whereas unsound, moldy, off-flavored feed will make itself manifest in the milk. Hence, producers of milk for city consumption, more than any other class of dairymen, ought to be exceedingly careful in regard to the quality of feed they give their cows. We suggest to our friend for trial, the following, as a minimum:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
17 lbs. timothy hay....	14.76	.48	7.48	.24
5 lbs. rye bran.....	4.42	.58	2.52	.10
4 lbs. buckwheat middlings.....	3.49	.88	1.34	.21
1 lb. oil meal..... ...	.91	29	.33	.07
Totals.....	23.58	2 23	11.67	62

In addition to the above, don't forget to give the cows a little salt every day, or better yet, with every feed. Salt is not only an excellent appetizer, but it materially assists in the digestion and assimilation of the feed, particularly of the protein elements.

HAS TO BUY ALL FEED.

Would you please formulate for me a balanced ration out of some of the following feeds: Wheat bran and middlings, 75 cents per cwt.; corn bran, 70 cents per cwt.; sugar feed, 66 cents per cwt, Quaker oat feed, 70 cents per cwt.; oil meal, $22.50 per ton; corn meal, 75 cents per cwt. I have plenty of corn stover for roughage. I have to buy all my feed, so I would like to have as economical a ration as is consistent with good results. W. C. W.

Dayton, O.

Where one has only corn stover for roughage, he should expect to feed quite liberally of grain, and especially of those kinds carrying a high per cent of protein. We are unable to find any analysis of "sugar feed" as such. We are inclined to think, if it is thoroughly dried, sweet and clean, it might be a profitable feed in this case, but the amount must be determined by circumstances. If used at all we should substitute it pound for pound for bran in the following formula, until we were feeding half bran and half sugar meal. We omit it from the formula, because we find no analysis of it, and suggest as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
25 lbs. corn stover....	14.90	.43	8.10	.18
10 lbs. bran.....	8.81	1.26	3.86	.30
2 lbs. oil meal.....	1 82	.59	.65	.14
Totals.....	25.53	2.28	12.61	.62

WEIGHING MILK.

I often seen it stated in your valuable paper about using scales and milk sheet. Now will you please copy a sample milk sheet in your paper for a milk shipper? And is weighing milk two days in the week enough to ascertain the amount of milk a cow will give in a year? H. H.

Albers, Ill.

The information as to form of milk sheet has already been given. The weighing of milk for two days in each week will give a very close approximation to the actual yield, and so far as that is concerned will answer all practical purposes. There are, however, some other considerations which make a record of each milking desirable. There is no other so sure way of keeping well advised as to the health of the cow and finding out whether each milker is doing what he ought to do.

A SOUTHERN CALIFORNIA RATION.

Will you kindly formulate a ration for me from following: Alfalfa hay $16 per ton; heavy bran (wheat) $23; whole corn ground fine $23; middlings $26; shorts $24; light bran (wheat) $23 I am not supposing that you will select all of above, but I submit them as a list.

Am feeding 25 cows, half of them Jerseys, quarter Jersey grades, and balance Holsteins and mixed grades. Am retailing milk and feed for good milk. This is our second dry year. Your advice and suggestions will be carefully noted by myself and many other suffering dairymen in this locality.

Los Angeles, Cal. S. P.

Alfalfa hay and ground corn supplement each other most admirably—the former being highly nitrogenous, and the latter carbonaceous. But it is not profitable to feed so highly concentrated material as corn without mixing it with something to greatly increase its bulk. This is accomplished in part by grinding the cob with the kernels, but even corn and cob meal is more concentrated than we like. Hence we often advise mixing bran with the meal, as well for its mechanical effect upon the other feeds as for its own nutritive properties, and this is one of the reasons why the light, flaky bran is to be preferred. Alfalfa hay cannot be said to be very cheap at $16 per ton, but it is much cheaper than bran at $23, and, if it is at all practicable to do so, we would recommend cutting 6 to 8 lbs. of hay and mixing it with an equal amount of ground corn, and then giving all the long forage each cow will eat. Otherwise we can do no better than suggest the following:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. alfalfa hay....	18.34	2.20	7.92	.24
3 lbs light bran.....	2.64	3.81	1.16	.09
6 lbs. corn.....	5.34	.47	4.00	.26
Totals.....	26.30	3.05	13.08	.59

A GEORGIA RATION.

Please give me a ration from the following feeds: Cotton seed meal $17 per ton; shorts, $21.50; corn meal $19; hulls $7.50.

Paschal, Ga. J. B. G.

This is not a very satisfactory list of feeds, either in variety or price, from which to suggest a ration formula. The cotton seed meal is cheap enough, but all the others are excessively dear. Moreover, hulls do not make of themselves alone very satisfactory roughage, and we do not much wonder that in another part of his letter, our correspondent refers to one of his cows being seriously out of condition.

Happily our friends in Georgia are, by this time, in the full enjoyment of newly growing pasturage, and this will go very far in modifying the feeding problems for the present. But now is the time to prepare for next winter, and we urge upon every reader of HOARD'S DAIRYMAN in the South the necessity of growing some appropriate and nourishing roughage for their cows. Many of the native grasses there, heretofore regarded as noxious weeds, make excellent hay, and there is the cow pea which should not be neglected on any Southern farm, or plantation.

We suggest to our friend that he mix cotton seed meal, corn chop and shorts in equal quantities by weight and feed from 6 to 10 lbs. of this mixture daily, as each cow seems to require, mixing each feed with an equal quantity, also by weight, of the hulls, and then feed whatever other roughage the cows will eat.

A MICHIGAN RATION.

Will you kindly formulate a ration of the following: Gluten feed, wheat bran, oat and corn meal, timothy hay, corn fodder and wheat and oat straw?

Gluten feed is a new thing for us, and we wish to give it a good trial, but do not wish to overfeed our cows. They are fair sized, and will weigh from 800 to 1,200 pounds.

We have plenty of oats and corn, and if the gluten feed is just as good fed with them would prefer to feed some, if not, will feed bran. F. W. S.

Belleville, Mich.

When one can get 2,300 pounds of bran for 2,000 lbs. of ground oats, it will pay to make the exchange. With timothy hay, corn stover and straw for roughage, there is not much opportunity for using corn in the ration for a milch cow. We are therefore of the opinion that more profit will follow if the corn and oats are sold, and bran and gluten, or other feeds rich in protein bought. When there is neither silage nor roots, we consider it a good plan to have some linseed oil meal on hand for use as may seem expedient. At present prices, one cannot afford to feed this oil meal simply for its nutritive value, but it has the virtue of putting the digestive tract in good order, and thus supplying the place of succulent fodder. With the near advent of spring pasturage, it may not be expedient now to go to any considerable trouble or expense to get oil meal.

Subject to the universal rule of making all changes gradually, whether in kind or quantity of feed, we submit the following formula, as about the least that one could expect to provide for an 800-lb. cow in fair flow of milk:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
10 lbs. timothy hay...	8.68	.28	4.34	.14
10 lbs. corn stover...	5.95	.17	3.24	.07
5 lbs. bran.....	4 41	.63	1.93	.15
5 lbs. gluten feed....	4.61	1.22	2.42	.25
Totals....	23.65	2.30	11.93	.61

CORN AFTER CORN.

Will you tell me through your paper, whether it will answer to raise three crops of corn in succession, if well manured with barn yard manure? Last year was the second year, and I had a better crop than the first year. I have but little good corn land, and would like to use that as long as I can in succession. J. B. W.

Courtland Co., N. Y.

Yes; but we would recommend sowing crimson clover in the corn each year, at the last cultivation, and plowing it under the next spring. This will add both nitrogen and humus to the soil.

COST OF MILK—PRICE OF PASTURAGE.

Since reading your paper, I have failed to see where any of my brother farmers have said what it cost them to make one hundred pounds of milk. Would like to hear from as many as possible. Have been doing some figuring in that line myself this winter and will report later.

Also would like to know what it is worth to pasture a cow during the pasture season.

Fond du Lac, Wis. W. S. W.

It would be excellent business sense for every farmer to adopt some system whereby he could know just what it costs him to produce milk. There is, probably, not one in a thousand who can answer this question. If dairymen generally had this information about their cows, there would be greater discrimination in buying and keeping dairy stock. It pays to keep and feed a good cow, and the better the cow the better it pays; but it does not pay to keep poor cows.

It is practically impossible to estimate the value or cost of pasturage. The price of land, its productiveness and other items make it very expensive in some localities, and very cheap in other places. By reference to his report, as published elsewhere, it will be seen that Prof. Smith, of Michigan, charges at the rate of 25 cents per week.

BUTTER IN FLORIDA.—CHEESE FROM ONE COW'S MILK.

We are trying to make Jersey butter in this land of sunshine and flowers, and as far as the making is concerned, we are succeeding very well. But it is the keeping qualities that is troubling us now. We have but one cow, period of lactation about six

months, gives eight quarts of very rich milk per day, from which we can make nearly one and one-half pounds of butter, but it will not keep more than a week before it will get strong, and we are as careful about cleanliness as we know how to be. The milk is strained at once through four thicknesses of cheese cloth and a wire strainer besides, cooled and aerated, and when the temperature did not go higher than 70° F. for weeks our butter would not keep. As soon as churned, we placed it on the shelf in the cellar, wrapping each roll by itself in parchment paper. Our feed is clover hay, Quaker oat feed, wheat bran, salt about an ounce in each feed night and morning. Cow has fresh artesian water by her all the time, and yet our butter will not keep satisfactory. This I should not think strange if it was confined to our efforts only, but since we have been making inquiries, we find that everyone in our neighborhood has had the same experience, and many are old butter makers in the North.

Others, it seems, were either ashamed to have it known, or believed it was in the climate, and no help could be had. I am confident we are at fault in some way, and I have no doubt but either the editor or some of the readers can and will come to our rescue. It was my intention to go into the dairy business more extensively, but as there is only sale for the milk during the tourists' season, we must depend on butter making for nine months of the year, and if we can not make a success of it, dairying will not be profitable.

One other question: Will it pay to make cheese from one cow? A SUBSCRIBER.

Florida.

It is possible that the temperature at which your butter is kept is the cause of your trouble. For keeping butter the temperature should not go above 50° F., and the lower the better. In a climate like that of Florida, it is not advisable to keep butter without ice. As a rule, the sooner you use your butter the better.

It is also possible that there may be some species of bacteria in your neighborhood that cause the butter to go off flavor. If you care to experiment, try pasteurizing the cream and add a little pure culture for a starter.

It will depend on the quality and size of cheese your market calls for. If large Cheddars are in favor, you could not hold the milk long enough to get sufficient for a cheese; if you can sell a small fancy cheese, it might pay.

A WISCONSIN RATION.

Please give me a ration out of the following feeding stuffs: silage, good corn stover, bright marsh hay, corn and oat meal, bran and linseed meal. L. A. M.

Almond, Wis.

Where one has only such roughage as is mentioned above, he must expect to feed more liberally of the expensive concentrates. The following combination would make a fairly good ration, much better than the great majority of cows are fed, but not as good as good cows deserve, when fresh or nearly so:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbo-hydrates	Ether Extract
20 lbs. silage	5.28	.26	2.80	.14
10 lbs. stover	5.95	.17	3.24	.07
6 lbs. marsh hay	5.30	.12	1.50	.05
4 lbs. bran	3.52	.50	1.54	.12
4 lbs. corn and cob meal	3.56	.26	2.52	.14
2 lbs. linseed oil meal	1.82	.59	.80	.14
Totals	25.43	1.90	12.40	.66

Here are 10 pounds of grain, but as no prices are given, we cannot estimate the cost We should much prefer to substitute 5 pounds bran and five pounds gluten feed, and we judge there would not be much difference in the cost.

TEST QUESTIONS.

Am having trouble with my tests. At times they are clear and pretty, and again they are just the opposite. A thick cloudy substance, resembling somewhat the "mother" in vinegar rises with the column of fat and intermingles with it. I use a preservative in samples when they are kept a day or two. Could using too much of this, cause the trouble. W. F. D. B.

Abilene, Tex.

You are probably using a weak acid. It should have a specific gravity of 1.82 to 1.83. When you buy it have the seller guarantee the correct strength. Keep it in a tightly corked bottle, as otherwise it will take up water from the air and become too weak. Do not try to read a test that is not clear. If it contains undissolved casein, as is probable in your case, you cannot read accurately. Bichromate of potash is the only preservative that is apt to cause trouble. It sometimes causes the casein to become insoluble in the acid.

FAIR PRICE FOR MAKING BUTTER.

Please give me what would be a fair price to pay a farmer's wife for the labor per pound on making butter. She does the work of taking care of the separator and working the butter on a butter worker. She has a man to do the lifting of cream, churning, and in fact all the other labor. The milk is separated by the man. Her labor consists of washing butter, tools and separator, and working butter, only. G. W. W.

New York.

We do not see how it is possible to give a satisfactory answer to the above question. The price to be paid per pound would depend partly upon the quantity of butter made each day, as it would take practically as much time to do the work for 20 pounds as it would for 50 pounds or more. Another element in the problem would be the degree of skill possessed by the butter maker. If she is capable of making an article that will command an extra price, her services would be more valuable than would those of one who was less competent. We think payment by the hour or the week, having regard of course, to the amount of work done, would be more satisfactory to all concerned.

A NEW JERSEY RATION.—CAPACITY OF SILO.

Will you please balance me a ration from corn meal, wheat bran, cotton seed meal, and dried grains, with corn fodder and timothy hay; cows weigh 800 to 1,000 lbs.

I am putting up a silo 12 feet in diameter and 24 feet deep, is that about what I want for 15 cows? J. R. B.

Allentown, N. J.

The following is about the minimum allowance for cows of the weight given and not yet commencing to shrink:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbo-hydrates	Ether Extract
10 lbs. timothy hay	8.68	.28	4.34	.14
10 lbs. corn stover	5.95	.17	3.24	.07
3 lbs. bran	2.64	.38	1.16	.09
3 lbs. dried grains	2.75	.47	1.09	.15
2 lbs. cotton seed meal	1.84	.74	.34	.18
Totals	21.86	2.04	10.17	.63

The first addition we should make to the above, providing there was no choice as to price, would be a pound and then two pounds of corn meal. After that, if we still wanted to increase the grain we would add a little bran or grains or gluten feed.

The grains should be thoroughly soaked and swollen before feeding.

A silo 12 feet in diameter and 24 feet deep will hold from 45 to 50 tons of silage and this will suffice for 15 cows 200 days, after making ample allowance for waste.

FERTILIZERS FOR CORN.

Will you also answer in the columns of your next paper your opinion of sowing the largest red clover in corn field just before running the weeder the last time, where you have manured about ten good loads per acre, broadcast and want to seed next year? I shall also use about two or three hundred pounds of fertilizer per acre.

Will you also give your opinion as to using kainit at $18 per ton delivered at our station, for corn, and use ten to fifteen loads of good manure per acre broadcast, or would it be better to use some other kind of fertilizer? My soil is of a heavy clay, and is capable of growing from three to four tons of hay per acre. How many tons should I grow of the Pride of the North, or some other large silo corn, grain and stalks?

Brushton, N. Y. B. M. O.

We can unhesitatingly recommend sowing clover as suggested, but if the crimson clover seed can be as readily obtained we should be disposed to try it, at least on a portion of the ground. There is some question about the necessity for using the commercial fertilizers in addition to the clover and barnyard manure. Kainit, or common land plaster (gypsum) can be used to great profit in the stable to fix and hold the nitrogen and thus serve the double purpose of conserving fertility and increasing the wholesomeness and sanitary condition of the premises. A pint each day per cow in the trench and on the floor and under each horse will be a good investment.

PRICES FOR MILK.

In this locality we sell our milk principally to cheese factories so our interest is centered in that direction. As it is now about the time that the milk is contracted for the season would like the prices given throughout the state if it is possible to obtain the figures.

The quotations would give us a better idea how to contract for the coming season.

Lamont, Wis. G. W. S.

We do not know where such a list could be obtained. The prices vary greatly according to location. For the prices at Elgin see page 115.

A NEW YORK RATION.

Would you give me a balanced ration for Jersey cows (fresh), weighing from seven to nine hundred pounds, from following feeds: Bran, corn and cob meal, oats, peas and barley, (mixed crop) weighing 58 lbs. to the bushel (mostly oats), hay, red clover, alsike and timothy (mixed), oil meal.

Stow, N. Y. L. L. G.

It is difficult to determine the exact feeding properties of mixed hay and grain, but we are of the opinion that a ration modeled substantially after the following formula, will give good results:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbo-hydrates	Ether Extract
18 lbs. hay	15.34	.86	7.13	.29
4 lbs. corn and cob meal	3.56	.26	2.52	.14
4 lbs. oats, etc.	3.56	.40	2.00	.16
2 lbs. oil meal	1.82	.59	.65	.14
Totals	24.28	2.11	12.30	.73

It is extremely probable that some of these cows could, profitably, be fed more. At all events, it is well worth trying. If you do not weigh your milk, commence to do so at once and keep a correct record, and increase the feed just as long as the increase in milk will justify it.

ALFALFA SEEDING.

Will alfalfa clover grow if sown in the wheat this spring, same as any other clover seed? Please advise me when to sow or if not to sow at all. E J. B.

Chester Co., Pa.

Sow alfalfa, without a nurse crop, in April, at the rate of twenty pounds of seed per acre. Alfalfa needs a fine seed bed, in ground free from weeds. The ground need not be plowed deep, but the upper three or four inches must be in fine tilth. Cultivate as soon as possible and then harrow every week or so until it is time to seed.

The soil should be free from weeds. Good

"A Word to the Wise is Sufficient."

But some stubborn people wait until "down sick" before trying to ward off illness or cure it. The wise recognize in the word "Hood's" assurance of health.

For all blood troubles, scrofula, pimples, as well as diseases of the kidneys, liver and bowels, Hood's Sarsaparilla is the effective and faultless cure.

Poor Blood—"The doctor said there were not seven drops of good blood in my body. Hood's Sarsaparilla built me up and made me strong and well." SUSIE E. BROWN, 16 Astor Hill, Lynn, Mass.

Dyspepsia—"We all use Hood's Sarsaparilla. It cured my brother-in-law and myself of dyspepsia. I owe my life to it." M. H. KIRK, 607 Franklin St., Philadelphia.

Hood's Sarsaparilla Never Disappoints

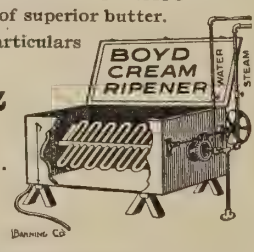
Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Gilt-Edge Butter

is the only money-making kind. But to make it, and the most of it, you must use the latest improved machinery. It is just this sort of product that has built up the demand for our

Empire Cream Separators.

They get all the cream from the milk and leave it in the best condition for churning. Lightest running and simplest in construction. Our catalogue will tell you why.



U. S. Butter Extractor Co., Newark, N. J.

BOYD CREAM RIPENERS stand ready to aid you to fortune with fame as a maker of superior butter.

Advertise Aerated Milk,

Mr. Milkman, and your trade will increase rapidly—you will get new customers, your old customers will buy more milk—give you a better price for it, too, if you ask it. If you want to know how to do it, write us and we will help you.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

results are reported by using a press drill and mixing the seed with an equal weight of wheat bran. Be sure and use enough seed.

A MILK TICKET SUGGESTION.

Can you suggest some better substitute for enclosed milk ticket? S. A.

Sheridan, Wyo.

If you prefer single tickets like the enclosed, there is but little chance for improvement.

Many dealers however, seem to like a ticket from which the record of the amount taken can be punched out.

The following ticket, originated by Mr. D. Seyster, was published in the DAIRYMAN in 1898:

SEYSTER'S DAIRY,
Maryville, Mo.

WHAT KILLED THE CALF.

Some time ago I lost a fine heifer calf about six weeks old. She had begun to eat hay, bran and corn stover, nicely; was still giving her about four quarts of milk twice a day, (milk had been heated to near the boiling point) was all right at night, in the morning we found her dead, badly bloated, little blood at the mouth, rectum looked as though she had been straining a great deal.

Elmer, N. J. H. W.

The most skillful veterinarian in the world could not answer this question. Some less skillful might attempt to do so, for fear an admission of not knowing everything would be regarded as evidence of incapacity. Too many doctors, and especially those who append M. D. to their signatures, jump at conclusions. For example: because they cannot assign any other cause for some unusual sickness among children, they will claim that it results from something fed to the cows which supply them with milk, and if it happens that silage is used, they will forthwith condemn silage, apparently oblivvious of the fact that milk from silage fed cows has been proven over and over again, in hundreds of thousands of instances, to be wholly innocuous.

Their reasoning is like this: If feeding silage to the cows did not cause this sickness I do not know what did; therefore it was silage. Conclusions based npon ignorance are not very reliable.

So in the case of this calf, one might hazard a score of opinions and still be far from the real cause of death. It is quite within the range of possibility that it ate too much of the hay and stover and got a mass of matter in the stomach that it could not dispose of and a stoppage was occasioned some where in the intestinal tract. It is also within the range of possibility that somewhere and somehow the calf picked up a nail or a piece of wire or something else which caused a perforation of the stomach. There are other possible causes of death, and, as we said in the beginning, no one can answer the question satisfactorily.

QUAKER OAT FEED.

We have been feeding corn silage, 20 pounds; wheat bran 3 pounds, and what clover hay and corn stover cows would eat. This is a wide ration, but the cows were doing well until we changed the bran for Quaker oat feed, when after about ten days the cows all went off feed, and scoured badly.

New Castle, Pa. F. E. M.

The sample of the feed did not come to hand. We can only say, that Quaker oat feed, as it leaves the mills, is an entirely wholesome and healthful feed, and well calculated to keep good and sweet. If this particular lot caused the trouble, it is one of the very rare exceptions, and most likely was damaged while in transit, or in being stored somewhere in great bulk.

CHURNABILITY OF CREAM. POOLING POOR MILK.

Do you consider that if the cream is properly handled in every respect, that one will always obtain all, or nearly all of the butter it contains? I have heard of at least two cases, on good authority, where persons kept only one cow, which, if the cow had been in a herd, it would seem probable they would have obtained no butter at all.

The first case was a minister who bought a cow out of a herd, and he could not get a pound of butter from her milk, churn as long as they would.

The other case was of a veterinary, with whom I was talking the other day. He said he bought a Red Polled heifer and kept her a year and sold her because the butter was either so slow in coming, or did not come at all, I can't tell which; but anyway, he said he had churned two and three hours on it.

It seems to me that when these cows were in their respective herds, it is probable that whatever butter fat was in their milk was lost. Do you think that in such a case as this it is probable that, with ordinary care of cream, etc., that they would get any butter from the milk of these two cows? If not, unless these cases are so rare as not to be taken into account, it would seem to me that the churn was really a more accurate test than the Babcock.

I have read in the DAIRYMAN, the inquiries in regard to the best breed of cattle, and your answers to them, but I am going to ask one just the same. Do you not think that where one had no very strong prejudice for any breed, that there is some breed that would have decided advantage over others, for certain purposes. For instance, would not the Holstein be far ahead of a Jersey for taking milk to a station where there is no account made of the quality, only that it must be up to the state standard?

Taylor, N. Y. E. B. C.

Much depends on the meaning of the term "properly handled."

A cow far advanced in lactation will give cream which is frequently impossible to churn by the usual methods of handling. With such cream it is frequently impossible to obtain butter, no matter how long the churning is kept up, and special methods must consequently be used for such cream.

There are also cows whose milk is sufficiently abnormal, either from the size of the fat globule or an excess of albumen, or from both, to yield but a small part of the fat in the form of butter. Such cases are not at all common, and in creamery practice such milk is diluted by the large mass of the other milk, and its vicosity removed so that it churns readily. A butter maker who understands his business, should know how to handle hard churning cream and get the fat out of it.

That there are men who do not understand such work, is no reason for taking a backward step, and using the churn for a test, especially when the rarity of such cases is considered.

If you want to consider only the present, without regard to your future profits, and if you are certain that milk will be always taken by weight, regardless of quality, then a herd of cows that will give a large amount of thin milk will be the most profitable.

But are you certain that such conditions are going to continue?

A WASHINGTON RATION.

Bran and shorts being my principal grain feed, with all the well cured oat hay the cows will eat, please give best proportion of shorts to bran. C. O. C.

Colfax, Wash.

Mix the bran and shorts, equal parts by weight, and feed 8 to 12 pounds daily.

This correspondent wrote us a long letter in regard to feeding, farm creameries, and other matters, some time ago. That was the trouble. We do not need to say that the past winter has been a universally busy one for this department, and it has been simply impossible to keep abreast with the demands. Both time and space have been wanting, and the long letters have necessarily been the first to suffer delay; but we give, in another place, a farm creamery plan, for his benefit, and that of others among the thousands of new names, which have been enrolled upon our subscription books since January 1st.

FEEDING IN NEW JERSEY.

I feed from 20 to 25 pounds silage daily, (fairly well eared, though not heavily) all the good mixed hay they will clean up, (it is hardly half clover, rest timothy,) and plenty of good corn stover. Now how should I mix bran and corn meal for best results? Can sell corn at 43 cents a bushel; bran will cost me $18.50 per ton, though what I have on hand cost $16.25; can buy Buffalo gluten meal at same price as bran, but never used any of it. Would it be cheaper than bran? H. W.

Elmer, N. J.

Corn at 43 cents per bushel when ground, will cost fully $17.50 per ton, and would be cheaper than bran at $18.50, but unfortunately one cannot feed all corn. Buffalo gluten feed has a much higher feeding value than bran, but, here again, we meet with the objection that it is not best to use gluten feed exclusively. We would advise mixing, and always by weight, five parts gluten feed with two parts each of the bran and corn, and feed from 6 to 10 pounds of this mixture daily, with the silage, hay and stover.

The new Sharples tubular separator has a bowl only four and one-half inches in diameter, and it revolves twenty-two thousand times a minute.

Catch Cold Easily?

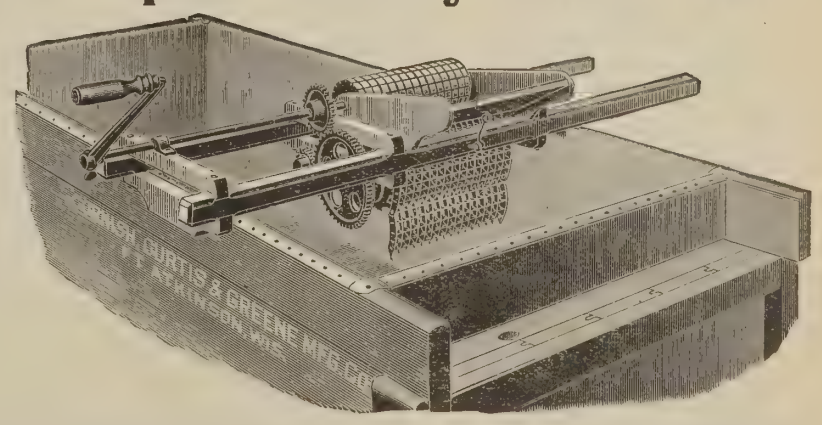
Are you frequently hoarse? Do you have that annoying tickling in your throat? Would you feel relieved if you could raise something? Does your cough annoy you at night, and do you raise more mucus in the morning?

Then you should always keep on hand a bottle of

Ayer's Cherry Pectoral

If you have a weak throat you cannot be too careful. You cannot begin treatment too early. Each cold makes you more liable to another, and the last one is always harder to cure than the one before it.

Dr. Ayer's Cherry Pectoral Plaster protects the lungs from colds.



Help at Hand.

If you have any complaint whatever and desire the best medical advice you can possibly obtain, write the doctor freely. You will receive a prompt reply.

Address, DR. J. C. AYER, Lowell, Mass.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

The Appeal of the National Dairy Union to the Dairymen.

The cause for being alarmed right now is the fact that during the past eight months the production of oleomargarine has more than doubled over the same eight months of previous year.

In eight months ending March 1, 1898, there were made in Chicago, 50-pound tubs of oleomargarine to the number of.....270,249

In eight months ending March 1, 1899, there were made in the same city, 50-pound tubs to the number of 534,434

What is the National Dairy Union?—It is an organization composed of those who are interested in dairying, and was the outgrowth of the necessity of some kind of an influence to check the inroads of fraudulent imitations which threatened a few years ago, as they threaten now, to displace so much pure butter as to make the keeping of cows unprofitable. Through the efforts of this organization the National Filled Cheese law was secured, and many state laws were obtained forbidding the sale of oleomargarine when colored to resemble butter.

Who are the officers who will handle this money? Ex-Gov. W. D. Hoard, of Wisconsin, publisher of HOARD'S DAIRYMAN, the best known of all dairy papers in the world, is president, and he succeeded to this position, the late congressman Hatch, of Missouri, who was father of the original bill which was passed in Congress in 1886, taxing oleomargarine 2c per pound.

The vice president is Hon. W. K. Boardman, late dairy commissioner of Iowa, president of the National Creamery Buttermakers' Association, president of the Iowa State Dairymen's Association, and one of the best known creamerymen in the country.

The treasurer is Hon. H. B. Gurler, of DeKalb, Ill., one of the oldest and most progressive dairymen in the famous Elgin district, and author of "*American Dairying.*"

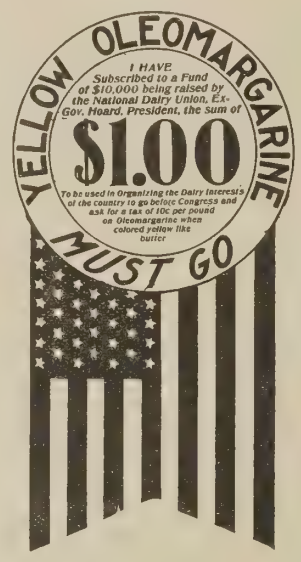
The secretary is Charles Y. Knight, editor of *Chicago Dairy Produce*, a paper devoted to butter making and the butter trade, and is known to practically every buttermaker in the west and the entire butter trade of the country.

All the officers give their time free of charge to this work, and aside from this the secretary's paper has subscribed $1,000 cash to the fund now being raised.

It will cost the leaders hundreds of dollars in cash besides their time to fight this battle in order that you may be protected from fraud. If they, who have looked into the matter, are willing to risk *hundreds of dollars*, shouldn't you who are going to profit, be willing to risk fifty cents or a dollar?

Why is money needed?—Because in order to secure congressional action upon any question, Congress must be convinced of its importance to a large number of deserving people. Hundreds of thousands of letters must be sent out to farmers in all parts of the United States in order to get them awakened and interested enough in this movement to circulate petitions and write letters to their congressmen and senators. Probably $5,000 will be spent in postage alone, besides the enormous amount that will be needed to pay for printing, and expense of representatives who must go to Washington and appear before Congressional Committees to argue this cause.

Money Talks, is an old and true saying. But in this case the *farmer's* 50c or $1 contributed, says to his congressman and senator:



"I want this law bad enough to go down into my pocket and help pay the expense of organizing to get it."

When they see the farmers that much interested they will know they mean business and will feel that the congressman and senator have done something for them if they vote for it.

Object of 10c tax—The object of the 10c tax on yellow oleomargarine is to make it cost the manufacturer so much to produce the outlawed counterfeit that he cannot afford to sell it to the retailer at such a low price that the latter will be tempted to palm it off as butter because of the big profit he can make selling it at butter prices. Unless there is a big profit the retailer won't run the risk of evading and defying our state laws. Now he can make as much as $6 a tub profit, selling oleomargarine for butter.

No escaping the tax—There is no such thing as escaping the tax if it is levied by Congress. Large establishments and capital are required to manufacture oleomargarine. Violation of the internal revenue law forfeits these factories to the government. There are only fourteen in the country, and they are not difficult to keep under surveillance.

What oleomargarine costs—Oleomargarine can be made at a cost as low as 5c a pound for a low grade. Paying a 2c tax raises the cost that much. The materials which take the place of butter fat are oleo oil (made from kidney fat of the steer), lard and cottonseed oil. Cottonseed oil costs about 3c per pound; oleo oil from 10 cents down; lard and grease from 6c down according to quality. These are mixed in different proportions and churned in skim milk, as a rule, and the whole colored like butter and put up in rolls and prints like butter. The cost of the finished product depends entirely upon the proportions and quality of materials used.

The manufacture and sale of yellow oleomargarine is now prohibited in 31 states with five-sixths of the population of the country; yet four fifths of all that is sold is sold in these same states in defiance of their laws. If your state prohibits the sale of yellow oleomargarine by law, why shouldn't your congressmen and senators vote to aid in enforcing these laws by placing a 10c tax upon the outlawed article? *They will if you will ask them to. But the farmers themselves must ask this.*

State laws are not enforced because the counterfeit is of such a character that it can not be detected except by chemical analysis. You might as well look for a needle in a hay stack as to endeavor to prevent oleomargarine being sold for butter so long as there is the inducement of a big profit in it.

The sale of oleomargarine is so damaging because it goes right to the market centres where our surplus butter should find sale, and there depresses the price of butter by being offered largely *as butter*, but at lower prices than we can produce butter from milk. While only a very small proportion of the butter made in this country is *consumed* in Chicago, New York, Boston and Philadelphia, it is those markets which *set the prices* for the entire country. When Chicago is filled up with oleomargarine, and large quantities are sold in Philadelphia and other markets where creameries might otherwise ship, they are compelled to flood New York and Boston with butter, which drives prices downward in every market in the country. Thus the overloading of the New York market alone will depress prices everywhere, as when New York drops every other market must do the same.

What this means to you—If you send the milk of five cows to the creamery, and they average 200 pounds of *butter* a year:

You are losing $30 per year or $2.50 per month if butter is lowered 3c per pound by this competition.

Gluten Feed

is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it.

Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating "Value of Butter Fat in Milk," all FREE if you address

THE GLUCOSE SUGAR REFINING CO.,

DEPARTMENT H. The Rookery, CHICAGO, ILL.

You are losing $20 per year if butter is lowered 2c per pound.

You are losing $10 per year if it is lowered 1c per pound.

What this means to patrons as a whole—If we are losing 3c per pound as a result of this competition, we are losing $1 80 per tub, and $180 per week, or $9,000 per year, if we make 100 tubs a week; $4,500 per year if we make 50 tubs per week, or $2,250 if we make 25 tubs per week.

If we lose only 1c per pound it would amount to $60 per week on 100 tubs; $30 per week on 50 tubs, or $15 per week on 25 tubs.

Don't you think, therefore, it is very important that we should become interested and aid this movement?

Oleomargarine manufacturers are protected against foreign competition by a tariff duty of 6c per pound, and an internal revenue tax of 15c per pound, a total protection aggregating 21c per pound. We are only asking for a 10c protection against a *counterfeit.*

Your name will be published if you subscribe. It will go in a report that will be placed in the hands of our congressmen and senators, showing them who are interested in this movement, and to what extent.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, X.

TETANUS OR LOCKJAW.

This disease is more familiarly known as lockjaw, but this appellation refers generally to only one phase of the malady, that in which the muscles of the throat and jaw are affected. The disease manifests itself by spasms, the muscular contractions often remaining rigid, rendering locomotion difficult, and at last impossible. The stiffened attitude assumed by the affected parts of the body, the legs, head, or ears, at once indicate the character of the disease. The eye is generally retracted, while the "haw" or third eyelid, i. e., the fold in the inner angle of the eye, is usually protruded. This disease is common to both man and beast. In the horse, donkey and mule, it often occurs; in cattle and sheep it is less frequent. It had long been noted that the disease generally bore some direct relation to injuries from wounds, but causal relation between it and a specific microbe was not definitely determined until recent years.

The phase which occurs in connection with wounds or bruises, is likely to be acute, and is generally most severe. It may arise as the result of almost any wound, but serious consequences are more likely to happen from those that are deep seated, such as punctures. The reason of this is evident, when the character of the germ causing the disease is known. The tetanus bacillus is an organism that cannot be grown in the air. It is what is technically known as an anaerobe, i. e., it grows under conditions where free oxygen of the air is not present. This explains why, in deep wounds, the chances of introducing the germ under more favorable conditions of growth are largely increased.

It may seem peculiar to learn that the germ is abundant in the superficial layers of the soil, but under such conditions, it is not in a vegetating, growing state, but a latent, spore form. The only way of access into the system is through the medium of wounds, generally external, but not necessarily so. Anything which pierces the skin, breaking its continuity, permits particles of dirt bearing the spores of this germ to be introduced, should they happen to be present in the soil.

The injection of a pure culture of tetanus spores is not usually accompanied with any serious results, but if foreign matter is simultaneously introduced, a development of the peculiar symptoms occurs. This is particularly true with matter that may contain pus-forming bacteria. Generally a rusty nail, or a pitch fork wound, unless quite severe, attracts but little attention, but it is just in this way that the germs of tetanus are often introduced. The significance of these dirt particles, then, is considerable.

The disease not infrequently follows castration, where the failure to properly dress the wound, affords an opportunity for the introduction of the specific germ.

The germ of lockjaw does not spread throughout the body, but its growth is confined to the point of invasion. Here it develops the poisons which are so potential. Already several distinct poisonous substances have been isolated from cultures of the tetanus bacillus. Some of these when injected into the animal system act in a manner comparable to strychnine. As most of these virulent products are soluble, they become diffused through the system. So powerful are they that a twentieth of a drop suffices to kill a mouse in little over a day. It is possible to render animals immune to the action of these toxines by continued injections under proper conditions, and the blood of such animals made refactory to the disease may possess in itself, the power to neutralize the action of the chemical poisons. This is really the basis of the so-called antitoxin treatment, now so successfully used in diphtheria in man. This system of treatment has been instituted in tetanus, but not so successfully, doubtless for the reason that it is rarely applied until symptoms of the disease have begun to manifest themselves, at which time the effect of the poisons is such that the counter treatment cannot overcome them. It is not improbable that the method of treatment may be so perfected in the future as to render it more efficacious.

At the present time the most practical treatment is that which concerns itself with the destruction of the tetanus microbe. In as much as this is found solely at the point of invasion (usually an external wound), it teaches the importance of speedy antiseptic measures in the treatment of wounds. The liberal use of carbolic acid wash (5%) or Creolin will effectually destroy not only the tetanus germ, but the pus producing bacteria that are invariably found in this class of wounds.

Reading to Profit.

Experience of a Maine Milkman.—Some of the Old Ways.—Questions of Pasteurization and Feeding.

Ed. Hoard's Dairyman:—It has been 17 months since I received a copy of the dairyman's friend, the Dairyman, and I can say, honestly and truly, it has been a revelation to me. I generally get it Saturday night, in the last mail, so I have a good chat with it on Sunday. I do not retain the whole paper but clip and paste all of interest in my scrap book, so I am getting a book of ready references.

Now I do not want to write a lot of nonsense to take up your valuable time, but I am in hopes you may be pleased to hear from me, for I have gotten all tangled up. When I first commenced to read the Dairyman I never dreamed there was such a lot of things about the dairy business, so I started in to know what there is to know through books and bulletins. The Director of our experiment station has been very kind to me in suggesting what books to get. Following his advice I have "Gurler's American Dairying," "Milk and Its Products," by Wing,

"Stewrt's Feeding Animals," "Breeding," by Miles, and Farmers' Bulletins, from the United States Department of Agriculture. In addition, I have the DAIRYMAN, which beats them all.

As you see, I am getting on the full armor, and if I am spared, and ever get started in the business, I expect to make some of the miserable wretches of milkmen, that are peddling cob webs and cow manure, either get out, or offer an article that is fit to use. What do you think of a man selling twelve 8-quart cans of milk a day from 13 cows, and having to buy half of this at the milk depot, where they claim to sterilize it, but is really only skimmed down to 3%, and some kind of coloring added. Then Mr. Man takes this milk to his home, and there it is mixed with his cob webs and cow manure, and he is feeding sour, moldy silage. He sells it for 7 cents per quart. I say such men are criminals and what is worse, if possible, these fellows do not know any better. If they did their conscience would condemn them. But I have not gotten at what I am writing you for.

First. I am studying as best I can the pasteurization of milk. I believe, from what I have lately read, that it is the coming process for preparing milk for immediate consumption. They say 155° F kills most all germs, but what are we going to do about the flavor it imparts to the milk? Will you give us some time, when you can spare the space, a few items in the DAIRYMAN as to the best practice of doing this?

Second. Suppose a cow weighing 1,000 pounds can use 2½ lbs. protein, per day, and she is fed 5 lbs., does the 2½ lbs. go off as waste, or is it used as carbohydrates, or lost?

Third. Can I obtain copies of the Wisconsin Dairymen's reports for 1895 and 1896? If so, where?

Fourth. Do Directors of Experiment Stations object to sending bulletins to others than those in their respective states?

Maine.

We do not much wonder that our friend finds himself somewhat "tangled up." Nevertheless, it still remains that "in the multitude of counsellors there is wisdom." It is not always possible at once to evolve one straight forward plan from these diverse suggestions, but a little patience and consideration will generally bring one out upon the high road. The books which our friend has secured would make a valuable addition to any dairyman's library. They make excellent general reading, and by a proper use of the indexes are invaluable for subsequent reference.

We should be much disappointed, if by referring to these indexes our friend could not find his first and second questions fully answered in these books, and, therefore, we reply in this place very briefly.

1. Pasteurization, when properly conducted, does not impart any bad flavor to the milk. The main point to be observed is, that no part of the milk treated should be heated above 155° F. This is very likely to happen, unless the milk is frequently stirred.

2. The extra protein in the case supposed would be used as carbohydrates, if it was needed, or there was not, otherwise, any excess of heat producing feed.

3. Copies of the reports of the Wisconsin Dairymen's Association for 1895 and 1896 can be had by addressing Secretary G. W. Burchard, Fort Atkinson, Wisconsin, and enclosing ten cents per volume, to cover postage and wrapping.

4. Bulletins are published primarily, for the residents of the state in which the station is located, but Directors do not usually object to responding to requests for copies from other states.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Board of Trade aggregated 9,840 pounds. All bids were at 20½ cents, and 1,380 pounds were withdrawn with this offered. The sales, aggregating 8,460 were all at 20½ cents, which was declared the market price with a steady market. The sales reported were as follows:

Factory.	*Pounds.*	*Price.*
McConnell	720	20½c
East Burlington	780	20½c
Shattock's Grove	2,460	20½c
Shabbona	1 800	20½c
Malta	1,800	20½c
Keystone	900	20½c
Totals	8,460	

The sales for the corresponding week of the three preceding years were as follows:

April 11, '98, 5,700 lbs of butter sold at 20c.
April 12, '97, 22,620 lbs. of but er sold at 16½@18c.
April 13, '96, 40,800 lbs. of butter sold at 16@17c.

The New York market Monday was reported steady at 21 cents. H. C. B.

Elgin, Ill., April, 10, 1899.

DAIRY MARKETS.

ELGIN, Ill., April 10—Butter—Steady, 22½c. All offerings, save 23 tubs withdrawn, were sold. Sales 141 tubs.

CHICAGO, Ill., April 10—Butter—Creamery, extra 19½@20c; firsts, creameries, 18@19c; seconds 15@16c; dairies, selections, 18c; No. 1, 15@16c; No. 2 12@12½c; extra ladles 14c.

Eggs—Fresh at mark, cases included, sold at 12½c.

Cheese—Full cream, Twins, good to choice, 11¾@12¼c; Cheddars 11¾@12c; Young Americas, 12@12¼c; Swiss, 11@13c; Limburger, 8½@10c; Bricks 11@13c.

Cattle—Receipts were estimated at 21,000, the largest run in five months, and nearly 5,000 beyond general expectations. Less than 1,000 straight Texas numbered among the arrivals. The proportion of choice to fancy native beeves was very small, considering the size of the receipts. Strictly prime steers would sell at 5 80@5.90, yet only one lot sold above 5 65. Fifteen 1,346-lb steers sold at 5.70, the highest sale reported. The general market was weak at 10@15c decline. Both Natives and Texas declined that much, while the best lots of cows and heifers were nearly steady. Most of the native beef cattle sold at 4.65@5 25; fed Western steers principally 4 60@5.15; straight Texas steers 4.10@4.25; Mississippi steers, 603@905 lbs, 3.75@4.12½; Missouri fed Texas, 1,190 lbs, 4.70; distillery bulls, 942@1.358 lbs, 3 90@3 95.

Bran—In fair request, but offerings very light and trading confined to 1 car, billed through at 11.50 per ton.

MILWAUKEE, Wis., April 10—Butter—Creamery, fancy prints per lb, 20c: extras 19½@20c; firsts 18@19c; seconds 16@17c; imitations 15@16c. Dairy selections, per lb., 16@18c; lines 14@15c. Roll, fair to choice, fresh, per lb, 13@14c. Market declining under increasing receipts, which are 10,200 lbs, while trade is moderate.

Cheese—American Full Cream, October Twins 11½@12c; Brick, choice 11½@12c; winter made, per lb, 11½c. Limburger, fall, choice, per lb, 9@10c; winter made, 8@9c. Swiss, drum, choice, 12½@13c; block, choice, 10½@11c. Market quiet and easy, with receipts of 20 boxes and 5 500 lbs.

Eggs—Fresh, per doz, 12@12½c. Market slightly higher, the demand being fair and receipts moderate; packers reported to be operating in the interior. Receipts, 872 cases.

NEW YORK April 10—Butter—Creamery, western, extras, 21@21½c; firsts, 20½@21c; state extras 20@21½c; firsts 20@20½c.

Cheese—State, full cream, large, colored or white, fancy 12¾@13c.

Eggs—State, Pennsylvania and Western, 13@13¼c.

ST. LOUIS, Mo., April 10—Butter—Firmer; creamery, 18@22c; dairy, 14@19c.

Eggs—Firm, 12c.

KANSAS CITY, Mo., April 10—Butter—Firm: creamery, 14@21c; dairy, 15c.

Eggs—Supplies light, market firm, though an increase of receipts is looked for this week Fresh Missouri and Kansas stock in new cases, cases included, 11c; cases returned, 10½c.

BOSTON, April 10—Butter—Creamery, extra, 21@21½c; western extra, 20½@21c; dairy, extra, 17@18c; imitation creamery, 15½@16c; western ladle, 14@14½c; print creamery, 21½@22c; box creamery, 21½@22c.

Eggs—Fancy near by, 14c; choice, fresh, 13@13½c; Michigan, extra, 12¾@13c; western, 12½@12¾c.

CINCINNATI, O. April 10—Butter—Steady, 21½c.

Eggs—Firm, 10½c.

Cheese—Good prime, Ohio fiat, 11½c.

NEWARK, N. J., April 10—Market steady, 21½c for best western, extra. Roceipts more liberal.

DETROIT, Mich., April 10—Extras, slow, 22c. Fancy dairy scarce, 16½c.

Eggs—Firm, 12½c.

Cheese—Firm, 13½c.

WASHINGTON, D. C., April 10—Market firm, extras, 22c; firsts, 21c, choice imitations, 18c.

NEW ORLEANS, La., April 10—Butter market quiet, 21½c.

BALTIMORE, Md,, April 10—Butter—Market firm; creamery separator, extra, 23@24c; creamery separator, extra firsts, 21@22c; creamery firsts, 20c; ladle, extra, 15@16c; ladle western, store packed, 11@13c.

Eggs—Market firm; strictly fresh stock, 12c; duck eggs, 13@14c.

PHILADELPHIA, Pa, April 10—Butter—Solid packed, separator creamery, extra, 22c; creamery, firsts, 21c; seconds, 19@20c; imitation creamery, extra, 18c; firsts, 16c; second, 14c; ladle packad, extra, 15c; firsts, 14c; seconds, 13c. Print Butter—Creamery, extra, 23c; firsts, 22c; seconds, 20c.

Eggs—Pennsylvania and near by, 13c; western, 13c; southwestern, 13c; southern, 12½c.

LIVERPOOL, April 10 Butter—Finest United States, 88s; good, 65s.

Cheese—American finest, white and colored, 52s, 6d.

BALTIMORE MARKET.

BALTIMORE, April 6—More activity has been noticed among receivers of, and dealers in, butter during the past week, and the cause is the very small quantity of goods arriving, and the almost entire depletion of accumulations of fresh lots and freezer stocks, and the desire of the buyers to secure enough for their daily demands out of the very little from which supplies can be obtained, and so there follows that the receivers, alive to their advantage, are very firm in asking slightly advanced prices, and the buyers in running around trying to find some receivers less obdurate than their fellows, multiply a moderate want into something larger than the reality, by being many times repeated. But apart from artificialities, such as just mentioned, it appears that a larger demand exists than can be satisfied by the regular receipts, and the most satisfactory solution to the trouble is for all who read this inducement to send forward liberal consignments of all varieties and grades, and they can rely on prices being maintained for several weeks at the present figures, or possibly higher. There is not a single lot of creamery left in the freezers, and very little of the other kind—ladles, not good but high priced. Blocks and prints of current make are in light supply, and are promptly placed at higher quotations. The receipts of rolls have fallen off to such an extent, that practically, they amount to nothing; the demand is active, and sellers could get a premium over quotations for all table grades.

Creamery Separator, extras, 22@23c; firsts, 20@21c; seconds, 18@19c. Creamery Gathered Cream, extras, 19c; firsts, 18c; seconds, 17c. Creamery Ohio, extras, 20@21c; firsts, 19@20c; seconds, 17@18c. Roll, extras, 14c; firsts, 13c; seconds, 12c. W. Va. Roll, extras, 13@14c; firsts, 12c; seconds, 11c. Creamery Blocks, (2 lbs.) extras, 23@24c; firsts, 21@22c; seconds, 19@20c. Creamery Prints, (½ lb.) extras. 23@24c; firsts, 20@21c; seconds, 18@20c. Md. Va. & Penn. Prints, extras, 20c; firsts, 18c; seconds, 15@16c.

Eggs—Are in fair receipt. We are glad to note that up to the present time, that the demand has kept pace with the supply; so far all receipts have been sold promptly on arrival. With a continued good demand, we write our market in good shape at 12 cents. Duck and goose eggs are in liberal supply, and the general tone of the market is quiet at greatly reduced prices from our last report. It is only a matter of short time that duck eggs will bring no more than hen eggs, if as much.

Cheese—Receipt light; demand good; market firm.

N. Y. State Cheddars, fine, 12@12½c; choice, 11@11¼c; fair, 9@10c. Flats, fine, 12@12½c; choice, 11¼@11¾c; fair, 9@9½c. Small, fine, 12¼@12¾c; choice, 12@12½c fair, 9½@10c. Ohio Flats, fine, 11@11½c; choice, 10½@11c; fair, 8½@9c. Picnic, fine, 11¼@12c; choice, 10@11c; fair, 9½@10c. Swiss cheese, fine, 11@12c; choice, 10c: fair, 8½@9c.

Pertinent Considerations

IN THE BUYING OF

A CREAM SEPARATOR

When you buy an "Alpha" DeLaval cream separator you know you have got the best that money and skill can produce; that you have got all that can be found in any other make or style of separator, and the all important advantages resulting from the use of the "Alpha" disc system in addition; that while you have paid a good fair price for it, you have something that is going to earn and save you money every time you put milk through it, and that if you ever want to sell it you can easily find a ready market for it at very little less than it cost you.

When you buy anything else in the shape of a separator, you know and everybody knows that you are buying something second-class at best, and something which whatever may be said of it, no one pretends to be the equal in all respects of the "Alpha" disc machines; you know that every time you put milk through it you are losing in a half dozen ways little considerations that an "Alpha" machine might save you; and if you don't know it already it won't require much investigation on your part to ascertain that if you should want to sell such a machine you will find it worth from $10.00 to $75.00, or very much less indeed than you paid for it, when you thought you were getting something possibly "cheaper" than an "Alpha" machine and made the purchase on that account.

It you would know more of the many differences between the "Alpha" disc and other cream separators, you will find them in complete detail in the new 1899 DeLaval catalogues—"Dairy" No. 279 and "Creamery" No. 509.

WESTERN OFFICES: Randolph & Canal Sts., CHICAGO.
GENERAL OFFICES: 74 Cortlandt Street, NEW YORK.
BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—Ten Guernsey Cows. Send particulars DUNHAM CO., 1392 Amherst St., Buffalo, N. Y. 9-2

Wanted—At once, a situation as butter or cheese maker. Five years experience. Understand all creamery machinery. Attended Dairy School in 1894. Good references furnished. CLARENCE WOOLCOCK, Platteville, Wis.

Wanted—At our dairy, near here, a thoroughly posted dairyman and milker, for position of foreman. Wages $35.00 to $40.00 per month and house rent free. Address, with full particulars of experience and references, MERAMEC HIGHLANDS CO., St. Louis, Mo. 9-2

For Sale Cheap—Four richly bred Holstein bulls from one to twelve months old. R. L. WALLACE, Box 851, Knoxville, Tenn. 8-2

Hermanville Tamworths, Cross-heds, etc. J. A. MACDONALD, Hermanville Farm, P.E.I., Can. 32-52

An Entire Carload—Of high graded Jersey cows and heifers are in my hands for sale immediatley. F. H. MERRELL, Portage, Wis. 52-tf

Wanted—Position by an all round dairyman. Can make cheese and butter. J. HEILKEMA, Holyoke, Ohio. 8-2

Position Wanted—By competent butter maker. 7 years experience in separator creamery. Can handle 9,000 lbs. of milk daily alone. Can keep books if wished. 6 years with one employer. Address L, care Hoard's Dairyman. 8-tf

For Sale—100 acres of land one mile from town of Crewe, Virginia. Crewe has 3,000 inhabitants. Norfolk & Western R. R., has its shops there. Also will sell milk route with farm. No competetion in milk business. $1,500 for both. Further information apply to T. O. SANDY, Burkeville, Va. 8-2

Wanted—At once, position on stock or dairy farm. Single. Experienced. Seven years at last place. References. Address F. R. R., care of Hoard's Dairyman. 8-2

For Sale or Rent—The Portage creamery, Portage, Wis. Immediate possession. Liberal terms to good party. WILLIAM FULTON, Prop. 5-tf

To Exchange—320 acres good Texas land, located 15 miles west of Beaumont, on So. Pac. Ry, and 3 miles from station. Will exchange land for Holstein cattle. Address A. R. CROUCH, Granada, Minn. 6-4

For Sale—Holstein-Friesian bull calves of choice breeding. Will sell cheap if taken soon. For particulars address, JOHN SHUGART & SON, National Military Home, Ind. 7-6

Wanted—A position by a first-class butter and cheese maker. Graduate of the O. A. C. Dairy School. Best of references as to character, etc. Correspondence solicited. O. D. LOCKWOOD, E. Coudersport. Pa.

Dairy Farm For Sale or Rent—First-class dairy farm for sale; 200 acres in grass; paying dairy already in operation, near town of 7,000 population, has only two dairies. Would take good man in as partner, or sell the outfit and rent farm. Address Box 691 Mexico, Mo.

Haunts in the Wild Woods and gay places for summer outings. Either or both, can be found along the lines of the Chicago Milwaukee & St. Paul R'y in Wisconsin, Minnesota, Northern Michigan, Iowa and the Dakotas. Among the many delightful summer resorts are Delavan, Waukesha, Oconomowoc, Elkhart Lake, Marquette, Madison, Kilbourn, Minocqua, Star Lake, Lakes Okoboji, Spirit Lake, Clear Lake, Big Stone, Frontenac, White Bear and Lake Minnetonka. In the north woods of Wisconsin, in the forests of Northern Michigan and Minnesota, and in the far stretches of the Dakotas true sportsmen can fish and hunt to thier heart's content. For pamphlet of "Summer Tours," and "Fishing and Hunting," apply to nearest ticket agent, or address with two cent stamp, GEO. H. HEAFFORD, Gen'l Pass, A't., 555 Old Colony Building, Chicago, Ill. 9 3

Experience with Cow Peas.

ED HOARD'S DAIRYMAN:—I notice quite a number of inquiries in the DAIRYMAN regarding cow peas. Now, as the cow pea has helped me out of many a tight place, I may at times be singing its praises too loudly, but before I start I will say, don't try to make cow peas take the place of corn or clover, in the corn belt.

This may seem to many an unnecessary caution, but I have too often seen men abandon good old stand-bys, and fly off on a tangent after some novelty, that some good catalogue maker lauded to the skies.

I have in mind just now, a man who, some years ago, got hold of a catalogue that boosted teosinte with words and pictures, as the forage plant of the age; our man planted his corn field with teosinte, and when harvest time came, he cursed all catalogues, all seed men, in fact, he cursed every body and every thing except himself, but he was very short on feed, and there was a sulphurous odor in the neighborhood of his farm for a spell that fall.

I recall another one who planted quite a field with sachaline or giant knot weed. He is as yet trying to get rid of the weed, and I have not seen a smile on his face for 36 months. No; corn and clover are our great stand-bys; that is, they will stand by us if we stand by them, but there is with them, generally, a place for some other good plants and the cow pea is one of them.

If our editor has the patience and the space in his paper, I will give a few bits of my experience with the cow pea, and incidentally will give my method of seeding and harvesting. Some years ago I purchased a worn out farm; some of the land was utterly abandoned and considered absolutely worthless. Nothing would grow on it, not even the weeds. I took an 11 acre field that was not farmed for many years and badly gullied. The last crop harvested from it, years before, was 17 shocks of rye, making less than 1 bushel per acre.

I dislike to make this matter so personal, but I wish to impress on the reader's mind the condition of the land, so as to more fully appreciate the value of the plant I am speaking about, and also the possibilities of apparently worn out soil. When I purchased the farm at public sale, it brought less than the buildings and improvements were worth, but the neighbors laughed at my "greenness" and kindly told me they pitied me, as I must surely starve on such God-forsaken land.

But to the field I was speaking about! I first plowed it very shallow, about three inches, and then made a very good seed bed, by the use of the roller, cultivator and harrow. I pulverized those three inches thoroughly. I now applied about 200 pounds of South Carolina rock, dissolved, carrying 28 pounds of available phosphoric acid, and 25 pounds of muriate to the acre, at a cost of about $1.50 per acre. I now sowed cow peas at the rate of six pecks to the acre, at a further outlay of $1.50 per acre. I sowed the peas broadcast by hand, and harrowed them in with the cutaway harrow.

The peas grew all summer, wet or dry, and when it was dry and hot they appeared to grow best, and by frost time in the fall, there was a mass of vegetation over that field, that astonished all beholders. I had planned, during the early summer, to plow the peas under, and seed the field to winter grain, but by September I had no heart to tackle that mass with a plow, and again I wanted it to grow to the last day.

The winter put it in a condition to turn under. In the spring I plowed the soil about six inches, and was astonished to see the change in the sub soil. What was formerly a tough, hard, unyielding mass was now broken up and pliable, easily plowed and readily put in good tilth with the cutaway harrow. I thoroughly incorporated the partially decayed vegetable matter with the soil, and planted the field to corn.

The yield was equal per acre, to land in the same vicinity that sold at public sale, for $40 to $50 per acre.

The following wheat and clover crops were good, and successfully and profitably grown. That field with proper management, feeding and cultivation has given me profitable returns ever since.

I feel conscientious when I say, those cow peas were worth to me $5 per peck, or in other words, the cow peas enabled me to start my soil on a career of usefulness, which enabled me to prove that my good neighbors prophesies were not always fulfilled.

My friend, if you have any such useless soil, or if your neighbor has any, it would certainly be worth the while to invest a few dollars and give the matter a trial, even though you are rather far north.

The plant grows very rapidly, during the hot months, and if it has a little potash and phosphoric acid to start on, it will take its nitrogen from the air, and get more mineral food by breaking up the soil particles, and thus makes plant food available for succeeding crops.

So much for a soil renovator! But while growing the cow pea to improve the soil, I discovered that it would fill a gap in my soiling crops that no other plant would. My early crops, including clover, Canada peas and oats would all ripen up or be cut for hay, while the corn crop, though planted early, would just be making its growth, and being very watery, was very unsatisfactory as a feed. I cut and fed some cow peas and immediately the milk flow increased.

The peas were very hard to cut, being a heavy mass close to the ground, vining and spinning over each other. I looked around for some plant to help support the pea vines, oats, wheat, rye, corn, etc., were tried, but all were smothered out very soon.

Sorghum did fairly well, but kafir corn fought its way up through, and stood up well above the pea vines and gave them a splendid support, making it much easier to cut the vines, and the cattle relished the kafir corn very much with the peas.

I use from a bushel to a bushel and a half of peas, and 3 to 5 lbs. of kafir corn per acre. Sow by hand and harrow in with the cutaway, or sow with the grain drill, though I prefer the former as being the quicker way. *I always want a fine, warm, loose seed bed, and not sow until the ground is warm and all danger of frost is past.*

I often sow the cow peas as a catch crop, after the strawberry crop is picked, or after the peas and oats are cut for soiling, or some other crop is removed. It not only makes me a lot of good feed, but holds all the fertility of the soil, and gathers some more from the air, and puts it altogether into a more available condition.

It makes good silage, especially if mixed with corn or kafir corn, as cut into the silo. Making hay of it is sometimes a little troublesome, as it is rather difficult to dry. The hay is excellent for stock. I stored some a few years ago that was only well wilted, but entirely free from dew or rain moisture, and it came out in fine shape. If the weather is very dry and the sun hot when we cut the vines, the leaves are apt to scorch, and we will lose them, if not careful in handling.

Experience will soon teach us the best methods of securing the crop.

A friend of mine sowed a small field for soil improvement, and when the first beans began to ripen, he turned in a lot of pigs, and in 8 weeks time they came out hogs. Yes, he said they grew like mushrooms, but when you came to handle them they were as strong as tigers, and the resulting pork was the finest he ever ate. Another neighbor of mine sowed some cow peas for his cows, but on account of a very wet season he did not need them for forage, but as soon as the beans began to ripen, his fowls started harvesting them, and from that time until late in the fall, while the hens of the country at large, were on a vacation and getting ready their winter clothes, his hens laid every day and the eggs sold at a very good price.

He told me not long ago that he never raised a more profitable crop and he proposes to repeat it.

Of course you all know the secret of the good flow of milk, of the good quality of the pork and of the abundance of eggs on the diet of cow peas. They furnish the protein out of which the animal can manufacture milk, lean meat or eggs.

I am not writing to recommend some novelty or boost something for some individual's benefit, but speak of a plant well known in many parts of the country, but not as well as it should be, and not appreciated as it should be in a large section. By the use of this plant we can improve our soil, increase our dairy products and cheapen production. Yes, it helped me to solve the problem, "How to make the farm pay."

Adams Co., Pa. L. W. LIGHTY.

A Word or So on Dual-Purpose Breeding.

ED. HOARD'S DAIRYMAN:—Perhaps nowhere has the general-purpose, or as the latter day saints have it, dual-purpose theories been more tested than right in this county, Oxford. And to-day, advocates of such breeding are as scarce as hen's teeth.

About 25 years ago, when Short-horns were first introduced, the cows were then all natives and crossing with the Short-horns did give in many instances good dairy cows, and part of this was, no doubt, due to the fact that the Short-horn of that day had some dairy qualities. I believe, however, a cross or two of any of the beef breeds, or native dairy stock, would in many instances improve their dairy production by giving to the grades so bred more vigor, and thrift, ability to assimilate food, but after a few crosses the predisposition to beef overcomes that for milk, and the further this method is pursued the worse the dairy qualities become. It will thus be seen that such breeding is a delusion and a snare. And so have our farmers found it here, until now, dual-purpose theories have no power to charm or ensnare.

It is true that the great majority, even among our dairymen, here prefer an animal of good size but this is not because of dual-purpose belief, but because our dairymen find that it is necessary to turn to beef some cows every year. In any dairy herd, this is always necessary owing to the many causes which make it desirable that some should be sent to the block; unfortunately dairymen have their troubles as well as others. We need only look to the veterinary column to see that. It will be noticed in a recent report of Mr. Tillson's herd his high average has only been attained by sending the less profitable ones to the block. Many small cows are retained too long because they will bring so little for beef, but even in this case first loss is best loss. When, however, a dairy cow is large enough to bring a good price for beef, there is a double chance that she will be sent to the block, when she becomes unprofitable in the dairy. Not that we believe in keeping a poor cow simply because she will bring $10 extra for beef, but rather do we believe in keeping a large cow that will make $10 more every year of her life and $10 more at death.

The difference in value of a small cow for milk and her value for beef is a very great tax upon the dairyman, because, in many instances a cow's usefulness is very short indeed. We had a cow get hurt only recently and it was necessary to make beef of her; she dressed 700 lbs. beef; such cows are worth something, dead or alive. But this does not prove that our cows are dual-purpose cows.

Prof. Shaw defines such, as an animal that does not excell in any one thing; and our cows do excell in the dairy as tests show.

Not only is there a great difference in the structure of the dairy and beef cow, but the rearing and developing animals for beef or dairy require different methods.

Beef breeds have attained their high excellency, by keeping the calves when young fat, and never let them lose the calf fat. This treatment for years gives the animal a predisposition to make beef, and turn all food into (beef) fat and growth.

An animal, intended for dairy purposes, requires quite different treatment. In this case, we don't want the predisposition to turn food into (beef) fat, but rather to make growth and build up a good constitution. And the heifer intended for the dairy is bred early, else upon attaining her growth, she may get the habit of putting the fat on her back, instead of in the pail.

It will thus be seen that the high standard reached by our dairy and beef breeds are both artificially reached by radically different methods. And being artificial requires constant care, or the work of 100 years may be lost in ten years; yes, five years.

We know a good dairy cow, bred as indicated, will make one third more milk and butter on same feed than another cow with the dairy qualities not so highly developed.

We also know now that a beef bred steer will make a larger gain than one not so bred. The difference in dairy profit in feeding a

good dairy cow or good beef steer will just be about one-third more.

It has been said by dual-purpose advocates that such large production by special dairy cows will lower prices until there is no profit. Well, large producers are admittedly the cheapest producers. We may easily see that the man with the dual-purpose cow will in time of low prices have no profit at all, must eventually be starved out. I don't see in that much to encourage a man to breed dual-purpose cattle. The same with beef; we know some will put on beef much faster and more economically than others, and will also from their superior qualities bring a cent or more a pound.

What farmers want is not dual-purpose stock, but the unprofitable cows should be culled out. A man will not get rich producing dairy products at a loss, even if he supplements his work by producing stockers also at a loss. There are too many doing this very thing. Feeders from this section buy, from outside, steers to fatten every fall; these are bought for from $20 to $25 at two and a half years old. No steer can be raised until two and a half years old for $20 or $25 and show a profit. Yet it is these sort of farmers the plea is made for on behalf of the dual-purpose animal.

I see in report of a meeting out west the speakers that advocate the dual-purpose idea said the farmers were not educated up to use special-purpose animals. The country has established experimental stations in every state and province on this continent to educate the farmers, and all professors and the press should use their utmost endeavor to educate the farmers in the right direction, and not as some are doing, try to pull down what others are building up.

Not only is there profit in doing work above the average, but there is pleasure also. I can myself take as much pleasure in pulling the milk from a great milker, as some can pulling the lines over a fast horse. And when I was a boy at home, and had the care of our beef cattle, we could always take pleasure in those of superior quality.

So as we lift our work up it becomes interesting and a pleasure. And it is in such a position I would like to see the farmers of this land rise to the dignity which their calling deserves, and not be "hewers of wood and drawers of water" for the rest of creation.

GEO. RICE.

Curries Crossing, Ont.

EFFECT OF PASTEURIZING SKIM MILK.

The question of some economical device for pasteurizing the skim milk at creameries, before it is delivered to patrons, is occupying the minds of many people, both creamery managers and patrons.

There is no denying that there is a most evident necessity for something of this sort. Skim milk, as it is received from a majority of the creameries, and as it is handled after it gets to the farm, is in many instances very distressing to the digestion of young animals, especially calves of tender age.

It is this fact which has given such an impetus to the idea of farm separators, and the cream taken to the creamery instead of the milk.

We believe this matter is of the utmost importance to the creamery interest, because it is of such great interest to the patron. Every well managed creamery will guard the patron's interest, all it can.

On this question of the greater keeping and consequent feeding value of the pasteurized skim milk, the following conclusions from the Fifteenth Annual Report of the Wisconsin Experiment Station may be of interest:

1. Two lots of skim milk taken from the separator at the same time, the one pasteurized kept sweet from twelve to twenty-four hours longer than the unpasteurized.
2. It was found that the attempt to use the exhaust steam from the creamery boiler was no more economical, than direct or live steam, and the latter is often more efficient.
3. The machine used was the Reid Continuous Pasteurizer.
4. It is absolutely necessary, in all cases, that the milk be at once cooled down to normal temperature, as fast as it leaves the pasteurizer.
5. The machine can be cleaned easily, and by using a very little care in turning off the heat when the supply of milk stops, the milk does not burn on the hot tin.
6. The greatest annoyance was the foam, which rises on the pasteurized skim milk, especially in hot weather, when such treatment is most needed. The milk residue, left from this foam, is very hard to clean from the tanks or floor, as it sticks very tenaciously, when the air escapes from the foam.

A Self Made Cow.

ED. HOARD'S DAIRYMAN:—A little more than a year ago I bought a common cow to furnish milk for the infantile Jerseys. Her owner "guessed" she was about half Jersey, but although she was of good dairy type, I concluded from her general make up that she must be a mixture of Short-horn, Ayrshire and scrub. At any rate, her origin was of so plebian a character that there was no family tree in evidence on which she might hang a phenomenal record.

At Sunny Peak Farm we earnestly strive to be impartial. Therefore, this cow was given a name and the same food and treatment accorded to her more aristocratic sisters. Her milk was as carefully weighed and her records as faithfully kept; she has never been "curried with a milking stool," but has received the same kindly care and daily brushing as the balance of the herd.

A short time since, in figuring up her milk record for the year, I found she had given a little over 132 cans of milk, testing fron 4.2% to 4.8%. As I have never received less than $1 per can for milk, and have been paid as high as $1.10, it will be no difficult task for any one to figure up the profit from this cow. Allowing $32 for food and care, you will, no doubt, readily see she has returned a good rate of interest on the original investment, which was $42. Had one been disposed to haggle a bit, I think she could have been bought for $38. However, what I want you to tell me is, how can I afford to part with Dame Dottie? MRS. ADA F. HOWIE.

Waukesha Co., Wis.

We confess to the same stress of mind that evidently bothers Mrs. Howie. Dame Dottie is evidently a "self made" cow, and did not need much help in the making. Stick to Dottie, for she is a money maker of the "purest ray serene" from the business side at least.

THE DAIRY COW.

In response to requests from new subscribers we republish the accompaning cut, giving outlines and location of the more important points to which reference is frequently made.

In examining the outline of a dairy cow, the first thing to attract notice is, that there are many points in which there is a decided deviation from the even and rounded outline of the beef animal. The central points of the dairy cow are her reproductive and milk generating organs, for it is from these that profit comes, and to them all other parts should pay tribute that they may be strong and well nourished.

For this purpose the typical dairy cow should have a strong jaw and large nostrils, for she must be a good feeder and deep breather; a full prominent eye, indicating large nervous force; the back bone large and strong, holding a large spinal cord, which is the conduit, if not the seat of vital force; a large and deep barrel, with ribs well sprung out to give room for storing and digesting large quantities of cheap and bulky feed; a strong abdominal wall to support the large and heavy digestive organs and their contents, indicated to some extent by its firmness, but more plainly by the depth and size of the navel, showing whether the fœtus was nourished through a strong, large, umbilical cord and thus born with a well developed, robust constitution.

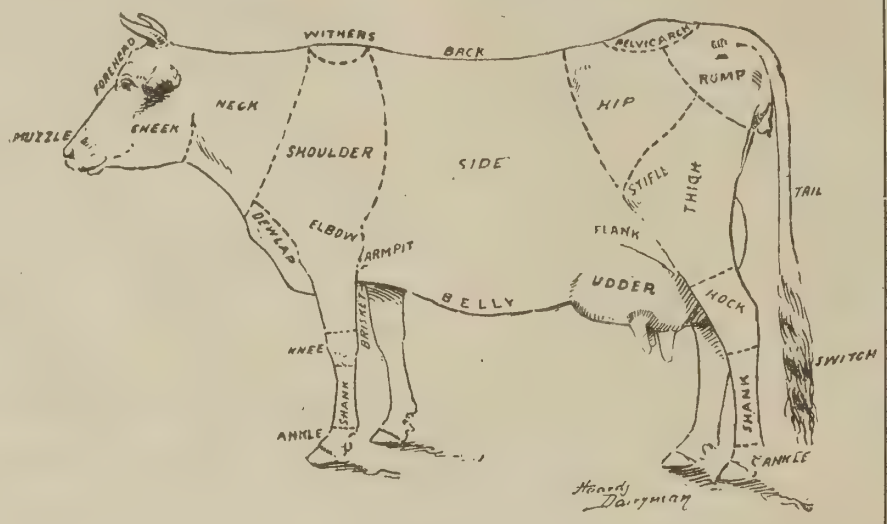
Having these accessories, the special-purpose of the dairy cow is more strongly expressed in the rear third of the body. Here she needs to have the large, symmetrical udder, rising high behind and extending well forward, with milk veins, large, tortuous in shape, and elastic to the touch. That the udder may have room, and not be cramped either in growth or activity, the flank should be arched at the side, and the thigh decidedly thin and incurving from the rear. If, to this enumeration, there be added a roomy pelvis, wide over the hips, and the back bone rising into an arch between them and towards the tail, the more distinctive points of a good dairy cow will be scheduled.

It happens quite opportunely that we are able to present, in connection with this illustration, Prof. Beach's carefully thought out modification of the scales of points for judging the dairy cow. A frequent reference, back and forth, from the article to the illustration, will bring out the salient features of each to better purpose than columns of comment.

The Creamery Product of Freeborn Co., Minn.

The annual reports of the various co-operative creameries are now being made, and they show interesting figures. The creameries at Geneva village, Hartland, Clarks Grove, Albert Lea, Alden, Riceland and Poplar Grove, seven in number, received 32,987,724 pounds of milk during the year just closed, and out of this milk, 1,410,977 pounds of butter was manufactured, showing that for the year it required about 23½ pounds of milk to make one pound of butter, the milk being a little better than 4 per cent. The total gross receipts of these creameries were $245,992.01, and the patrons who furnished the milk received $217,616.26, showing the total expense of operation, sinking fund, etc., for the seven to have been only $28,375.75, or a little over 10 per cent of the gross receipts. Of course, these figures do not include the buttermilk and skimmed milk the farmers have for feed, and which is estimated to be worth 15 cents per hundred pounds.

There are nineteen other creameries in the county, but several of them are small; still the gross receipts of the twenty-six will reach nearly three-quarters of a million dollars for the year just closed, and the net amount paid patrons will be not far from $600,000.—*Minneapolis Journal.*



A New Scale of Points for Judging Dairy Cows.

ED. HOARD'S DAIRYMAN:—It is fair to assume that the breeders of the various dairy breeds are each striving to produce an ideal dairy cow. In a study of the types of the various dairy breeds by means of their official score cards, respectively, the student is confused by the disagreement and lack of harmony in the respective scales of points.

This lack of harmony is manifest:

1st. By an absence of any system in arrangement of points.

2nd. By different values assigned to the same structural development.

OUTLINES AND POINTS FOR JUDGING AND SELECTING THE DAIRY COW.

3rd. The different score cards are at variance as to the points or structure which should constitute a typical dairy cow.

To illustrate: The Holstein score card allows 12 points in one hundred for a perfect udder, the Guernsey 26 points, the Ayrshires 30 points, and the Jersey 34 points.

For a perfect escutcheon the Holstein and Guernsey allow 8 points, the Ayrshire 3 points, and the Jersey nothing.

For the color of skin, texture, and fineness of hair the Jersey and Ayrshire allow 5 points, the Holstein 10 points, and the Guernsey 30 points.

To avoid the confusion which must arise in the mind of the student from an acceptance and application of these various standards, the following score card has been adopted with us and used (irrespective of breed) in our study of dairy cows. This score card is based on some knowledge of the physiology of the cow, as well as on a comparative study of the form of typical dairy cows. An attempt has been made to incorporate the few following ideas:

1st. The dairy cow must have a large digestive capacity, and hence a long, deep and well sprung barrel.

2nd. Milk is a manufactured article, and the need of roomy laboratory or udder is apparent.

3rd. Milk is secreted in the udder from the blood, and hence the size of the milk veins becomes an indication of the amount of blood that can be carried through and away from the udder.

4th. The digestion of a large amount of food and its subsequent manufacture into milk must class the dairy cow as a hard-worked and wonderfully active animal. The need of a well developed nerve system to guide, superintend and control the functions of the highly developed organs of digestion and secretion is imperative.

5th. The dairy cow must then be spare, depleted of all superfluous flesh, in order to be an economical and persistent milker.

In designing this score card, we have adopted the suggestion of the editor of the DAIRYMAN of dividing a cow into three portions by drawing two perpendicular lines, one just behind the withers, and one in front of the udder. To the front portion we assign 13 points; to the middle, 20 points; to the rear, 34 points; and in addition, we allow 33 points for indications of a persistent milker.

Many dairymen are excellent judges of dairy cows. My father used to think he could go into a neighbor's herd, and pick out his best cow. I believe he could do this, but I am equally sure he never taught me the secret, nor was the gift inherited. This

Two Wagons at One Price.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn fodder, wood, stones, etc. The man who already has a wagon may have one of these low handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments time. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., Box 130 Quincy, Ill. for their catalogue; which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

Park Farm Jersey Dispersal Sale, April 26, 1899

Of **25 Registered Jerseys and five Grades.** At head of herd and for sale, Butler Stoke Pogis, 27290, a son of Ida's Rioter of St. Lambert, 13656, sire of 29 tested daughters; also a grandson of Stoke Pogis 5th, sire of 24 tested cows and over 120 tested granddaughters. Also 4 tested cows and their descendants, about 18 head; and 2 cows of Stoke Pogis 3rd, sire of 27 tested cows; Regina, 20 lbs. 4 oz.; Miss Porter, 16 lbs. 6 oz.; Violet 3rd imp., 15 lbs. 8 oz.; Coomassie, 16 lbs. 11 oz.; and Old Noble breeding. Two first-class yearling bulls, dams, tested cows, three grand-sons of Ida's Rioter of St. L. 13656, and some heifer calves same sire. Send for catalogue to the JERSEY BULLETIN, Indianapolis, Ind., or EVERETT G. CAMPBELL, Kiesters, Pa.

score card is an attempt to give expression to our common knowledge of the dairy cow, and put in teachable form our knowledge of the structural points.

No claim is made to originality in treating this subject. My intenre interest in this study of the form of the dairy cow has been pr mpted almost entirely by the reading of HOARD'S DAIRYMAN. This subject has been discussed many times in its columns, and scarcely an issue appears that does not treat of or illustrate and emphasize some of the points of the dairy cow.

STRUCTURAL POINTS FOR JUDGING THE DAIRY COW.

Indications of a Large and Economical Producer.

FRONT. 13	Wide between eyes. Eyes prominent and bright. Wide juncture of brain and spinal cord.	6	
	Muzzle wide.	1	
	Shoulders light and sharp withers. Fine neck and head. Brisket V not U shaped.	6	
MIDDLE. 20	Barrel long and deep, with well sprung ribs	10	
	Milk veins prominent, extending well to front, eyelet large.	4	
	Backbone prominent. Crops scant. Ribs and vertebræ wide apart	4	
	Chest deep.	2	
REAR. 34	Udder: Extend well to front and up behind, must not be too fleshy teats even and squarely placed.	17	
	Deep from h'p bone down.	4	
	High arching flank and cat ham.	8	
	Hips broad and pelvic arch prominent	4	
	Long slim tail.	1	
		67	

Indications of a Persistent Milker.

Lean, spare, light front and rear quarters, scant crops, lacking superfluous flesh.	33
Total	100

Our Short Course Dairy students have just finished scoring the college herd whose record appeared in the DAIRYMAN of March 24. These students had no previous experience in judging animals, and the averages below are the result of their first efforts.

The practice in scoring was preceded by a few talks or lectures on dairy form and the physiology of the cow. Usually, four cows, stable companions, were scored at a time, each day, and the scoring continued until the whole herd had been gone over.

Column one gives stable number; column two, the net profit based on prices and credits given on page 113 of the DAIRYMAN; column three gives rank of individuals, according to net profit; column four gives rank according to average score; columns five, six and seven give average, maximum and minimum score by students.

Stable No. of Cow.	*Net Profit for 1 Year.*	*Rank according to Net Profit.*	*Rank according to Score.*	*Average Score.*	*Maximum Score.*	*Minimum Score.*
2	42.82	1	1	92¼	94	86
1	40.42	2	2	87.7	89	84

21	2.32	21	20	60.	64½	55
24	−2.66	22	21	58.9	65	56
25	−4.09	23	23	50.	54½	43½

Cow No. 15 injured her udder, and as a result, her record for this year is 120 pounds of butter less than last year. On this account her rank in the herd is lower than the score.

Blood does not always tell. No. 23, on her sire's side, carries in her veins the blood of Stoke Pogis, Lord Lisgar, Orloff and Lilly, Lucy and Cheerful of St. Lambert. Her dam was of an imported standard cow, and yet she made only a profit of $3.47 for the year.

No. 20 came from one of the oldest and most noted herds of the kind in this country. With one exception she cost the most money of any animal in the herd, and yet made a profit of only $4.92.

No. 25 holds the highest record for pounds of milk for one day, of any cow in our herd. She came to us with the reputation of a heavy milker, and yet her record for the whole year shows a loss of $4.09.

We are constantly judging cows by false standards—breed, pedigree, reputation of breeder, records for one day or one week.

As dairymen, we must become better judges of the cow, by studying her form, by studying her physiology, by studying her individuality. C. L. BEACH.

Storrs' Agricultural College, Storrs, Conn.

Comments on Former Issues.

Milk Trusts and Skim Milk.

ED. HOARD'S DAIRYMAN:—On page 103 (March 24) HOARD'S DAIRYMAN makes some good suggestions as to how farmers should guard themselves against being the toys of the milk trusts. I think it exactly the correct thing for farmers to unite and establish a well arranged creamery, at least, at some of their best shipping stations, so that, whether trust or no trust, they never are compelled to overflow the city market with their surplus milk, when the city does not need it.

Besides every farmer, or rather collection of farmers, who possess such a creamery, will soon find that who ever may be the receiver of their milk, they will be able to secure far better terms and prices, if they can agree, within certain reasonable limits, of course, to furnish more or less milk or cream on short notice, as the demand may be. And this they can only do without serious loss of the surplus, by having a well arranged creamery.

As to the utilization of the skim milk, when a surplus of milk is at hand, and the price for butter is favorable, I would suggest that all such creameries should be arranged also for making cheese, and be provided with proper curing room. It is still one of my hobbies that a well made, well cured skim, or partly skim cheese is far more palatable than a badly cured full milk cheese.

We should always keep in mind that many of the high priced, imported foreign cheese, like Parmesan, Gouda, Edam, etc., are made either of partly skim milk, or of milk containing only 2½ to 3 per cent fat, as most milk in Holland does; and even then, often the cream is taken off the night's milk before it is used with the morning's, thus absolutely being only equal to a half-skimmed 4% milk, such as we generally have.

I am sure that at such a shipping station creamery, especially where one day all milk has to be shipped, and on another we may have quite a surplus, it will pay better to make a partly skimmed cheese than feeding pigs and calves, as such are badly served by getting plenty of milk one day, and possibly none the next.

BUTTER MILK FROM SKIM MILK.

On page 104, Mr. Taylor Stratton, of Tennessee, claims that it is impossible to make a "good, old Southern butter milk" from separator skim milk. Now I can assure Mr. S. that I have done so right along, and had many customers in Tennessee and Kentucky, who absolutely preferred such buttermilk that was made from skim, to the genuine; the whole secret is in the ripening. Ripen just as carefully as you would cream, and churn when the milk has barely clabbered, and don't wait till it thickens too hard, and you will have as smooth, thick and fine flavored butter milk as any one can desire; but if it stands too long and warm before churning, the curd will separate from the whey and will sink to the bottom, and you have a watery, poor looking butter milk, no matter how much you stir it afterwards.

I know both breeds only too well from experience. Try it again.

Pasteurized skim milk, ripened with a good sour skim milk starter, will make a smoother and finer butter milk than any other.

WHIPPING CREAM.

On page 108, HOARD'S DAIRYMAN answers a question as to why separator cream would not whip. Of course it was too thin; but I guess it was a slip of the pen when HOARD'S DAIRYMAN states that it should contain 20% fat; here in Washington, D. C, no cream is allowed to be sold with less than 20% fat, and what here is called "whipping" or "double" cream should contain, at least, 40% fat; 20% cream sells here at 30 cents per quart, and "double" cream, 40% fat or even 45%, at 60 cents per quart.

SALTING AND WORKING BUTTER.

On page 114, Mr Rockwood gives such a queer method, certainly not up to date, as to this work. Now, while he may succeed in producing an article which pleases his customers, still I would advise other farm-dairy buttermakers to be very careful in adopting that method. I am sure most will succeed in having mottled or overworked butter. Any experienced, up-to-date buttermaker will agree with me that the directions do not agree with modern methods. As to the adding of salt before finishing churning, it seems to me very objectionable to ruin all your buttermilk by so doing, and you can make just as perfect butter without putting any salt into the churn.

WHY CREAMERIES DO NOT PAY.

Mr. Scott's remarks on that point, on page 120, have my fullest endorsement. I have always thought that an individual owner of a creamery, especially if a practical butter and cheesemaker himself, is far more liable to make the business a paying investment, than a stock company.

The one difficulty in the way seems to me to be, that whenever a buttermaker buys a creamery, many patrons are so selfish and short sighted, that they try in every way to cut down his profit, being afraid he will "get rich" too fast. The better off he gets, the more sure they ought to feel that he will stick to the job, and do the very best he can, and that his profit always, finally, will mean their profit also; his loss is sure to mean their loss. Can't you see it?.

Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

HOLSTEIN BULL
A BARGAIN.
In Letta Wit's Jewel we offer you one of the best of the breed. He was dropped Aug. 18, 1898, nicely marked, straight on back, deep well ribbed barrel, thin neck, fine head, rich golden skin, large mammary veins and teats, and a dairy animal of the highest order. He is sired by Mechtchilde Jewel Henry Colantha 22153, and out of the imported Aaggie cow Letta Wit 368. She has a milk record of 84 lbs., 2 oz. in 1 day, and a butter record of 22 lbs. 4 oz. in 7 days. He is backed by the greatest prize winners of the breed as well as the greatest milk and butter cows. He traces to Mechtchilde, 112 lbs. milk 1 day, 39 lbs. 10½ oz. butter in 7 days. Jewel, 100 lbs. milk in 1 day, 31 lbs 3½ oz. butter in 7 days. Colantha, 89 lbs. milk in one day, 31 lbs. 7 oz. butter in 7 days. Teetje Janzen, 30 lbs butter in 7 days. Oude Empress, 114 lbs. milk in 1 day. Empress, 109 lbs. milk in 1 day. Mantado, 95 lbs. milk in 1 day, and a large number of others of great merit. In short, there are 20 cows in his pedigree that average over 100 lbs. milk in 1 day, and 30 cows that average over 90 lbs milk in 1 day. If you want him write at once. Price $50 00.
Wis Live Stock Association, Appleton, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to J. A. THORNTON, Mgr., Simonsville, Vt.

Ten Choice Yearling
Holstein-Friesian Bulls
FOR SALE!
Sired by sons of Parthenea's Colanthus, whose dam had a record of 38½ pounds butter in seven days. Write for description and prices.
A. H. WEGEMANN, Lake Mills, Wis.

BLOOD WILL TELL.
To intending buyers of Holstein-Friesian Bulls, who wish to obtain the highest possible results in dairy line, we say: "Get the blood direct from the foundation of the greatest butter families." Then success can be assured. "Valley Mead" is headquarters for H.-F. cattle, an therefore is able to give you a larger per cent of blood of all the greatest butter families of present and former days than can be procured elsewhere. Address,

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. F. W. TRATT, Whitewater, Wis.

M. D. Cunningham,
KANSASVILLE, WISCONSIN.
Has for sale two male Guernsey Calves; one dropped April 1st, 1898 and the other Sept. 8, '98. Excellent animals.

Riverside Guernseys.
CHAMPION HERD
AT NEW YORK STATE FAIR,
1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by COMUS, sire of most of the winners, for sale. Thoroughbred Poultry—the best egg-producing and general purpose varieties—Leghorns Wyandottes, Buff Ply. Rocks, Houdans. Send for circular. Stock for sale. J. FORSYTH, Riverside Farm, Owego, Tioga Co., N. Y.

Florham Guernseys.
I offer at attractive prices TEN BULL CALVES from one to seven months old. Most of them were imported in dam and are of the best English and Island strains.
J. L. HOPE, Farm Supt., MADISON, N. J.

GUERNSEYS.
225 Pure Bred Guernseys,
Of the best American and Island breeding. Butter average, whole herd, 318 lbs. per head. No catalogue. Come and make your own selection.
ELLERSLIE STOCK FARM, Rhinecliff, N. Y.

MILLWOOD FARM
Guernseys!
Guernseys of All Ages and Sexes For Sale.
Bred from Tested Dams. All animals have been tested with tuberculin and certificate of same is provided with each animal.
N. I. BOWDITCH, Framingham, Mass.

Preparing for Another Season's Crops.

More Attention to Clover Seeding and Make Calculations for a Crop of Oat Hay.

ED. HOARD'S DAIRYMAN:—As the DAIRYMAN circulates so largely throughout the United States, the writer who would adapt his articles to the conditions of this extensive territory, must be "instant and in season" in order that the greatest number may be benefited.

Of course the wide-awake, observing farmer has largely perfected his plans for the season's work, but such are ever on the lookout for any suggestions that will be of benefit to them.

The DAIRYMAN has always taken a very decided stand in favor of the production of clover for hay, and I think as farmers come to know more of its value from practical experience, the better they will like it.

Last year the clover was good and it was secured in excellent condition, thus making it of the best quality as fodder. We have found this fine quality of hay, when fed in connection with ensilage and a moderate amount of grain, composed of bran, gluten and cotton seed, to produce excellent results, as good as could be expected from the best summer pasturage. A trial of one feed a day of clover hay and one of timothy resulted in such a decrease of milk and butter that the timothy was dropped, and after a time the yield began to regain. The clover is much preferred to timothy by the cows, which is pretty good evidence of its greater palatibality and value.

One difficulty will be in raising sufficient clover hay on many farms for the use of a winter dairy. This will require a shorter rotation than is usually practiced by farmers. Where corn is grown largely for the silo or to cure, this will render a more frequent seeding for grass necessary, and thus help to accomplish the object sought.

In our experience here, we find that a mixture of red and alsike clover and timothy make a good combination for hay of best quality, superior to that from red clover alone, and is not nearly as difficult to cure.

In the West and South where alfalfa and crimson clover are so successfully produced, it is possible to have a greater variety of fodder plants, as well as a larger yield.

Here we usually seed to grass in spring along with a crop of grains, now largely oats or barley, as wheat is little grown in Vermont.

The earlier this seeding can be properly done the better it will be. Three pounds of alsike, six or eight of the red, and enough of the timothy to make half a bushel in all, is sufficient for an acre. This makes a liberal seeding and under favorable conditions, should be followed with good crops of the best quality of hay, particularly as the timothy will be secured at an early stage of growth. Another thing, the first season the proportion of timothy to the clover will usually be comparatively small, but will increase the second and third years, when it will finally take the place of the clover; hence the necessity for a shorter rotation in order to secure more of this valuable fodder.

On the average farm there is generally a considerable amount of grain raised, and in my own state, this is getting to be largely oats.

If the greatest benefit is expected from a dairy of cows the less of straw that is consumed, the better it will be. Where winter dairying is practiced, it should have no place as a fodder, but may be liberally used as bedding for the stock, the compensation, therefore, being in increased comfort and cleanliness of the animals and the larger amount of manure made.

Experience is proving that it will be more profitable for the farmer to harvest a part of his oat crop as hay, instead of allowing it all to mature and be threshed. Calculation for this should be made at sowing, as some pieces or fields might be more desirable for this purpose than others, and it might be better to sow more thickly than were the crop to be threshed. Last season one piece was harvested quite early for hay. The growth of straw was tall and large, the yield being heavy. Naturally the quality of this would not be as good as a shorter and finer growth, yet it was eaten and relished by the cows, there being practically no waste Only one feed a day was given and while it lasted, which was about two months, the cows appeared to do as well as when fed with hay.

I think where a considerable acreage is devoted to this grain, it will be found more profitable to make a portion into hay, as experience is proving this to be the case from year to year.

As with this practice the crop does not remain as long on the land as when allowed to ripen, there will be a better chance for the grass seeding, and particularly if care is taken not to cut the grain too low.

Franklin Co., Vt. E. R. TOWLE.

A Year's History of a Grade Short-Horn Herd.

Some Exact Figures and Conclusions Therefrom.

ED. HOARD'S DAIRYMAN:—Allow me some comment on Bulletin 166, which I send you herewith. It is the history of a grade Short-horn dairy herd, hastily gotten together in September and October 1897, and properly cared for and fed for a year, keeping a strict account of the cost of care and feeding. Of the twenty-nine animals purchased, one was seriously injured on arrival at the college, another was condemned as tuberculous in the spring of 1898, and a third gave bloody milk to so great an extent, as to prevent the use of her product in the dairy, and she was forced to veal the calves of her mates in the herd. Misfortunes of this kind are bound to happen occasionally, and the accounts with these three unfortunates were included in the financial statement.

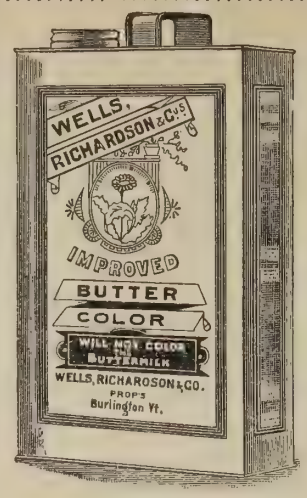
It costs us five cents a day, per cow, to get the milking done, except for the cows milked by the regular herdsman. The average cost of the labor involved, and the butter making, milking and caring for each cow was $21.19, an amount inordinately large, undoubtedly, owing to the expense of milking. The cost of the feed per cow was $35.96, which includes the pasture. The net profit for the herd, as a whole, was $277.58

The milk was made into butter in the fall, and the butter sold at prices varying from 20 to 22 cents. During the winter the milk was sold to the college dairy at the price paid for milk from outside sources, $1.20 per hundred. During the summer of 1898 the cream was sold, as far as the markets would take it, at 60 cents a gallon, except some at retail, which went at 80 cents. The milk not needed for this cream trade was worked up into butter, which sold at from 15 to 22 cents per pound.

The summarized account is as follows:

THE GRADE HERD.—DR.

29 cows at $39.51	$1,145 69
Care and milking	520.51
Making and selling 2,302.5 lbs. of butter at .03	63.08
Salt	6.43
Green clover	.96
105,807 pounds of silage	119.74
94,310 pounds of hay	266.54
42,427 pounds of bran	270.87
31,068 pounds of corn meal	236.98
57,705 pounds of beets	72.10
21,279 pounds of corn stalks	25.13
4,400 pounds of linseed meal	40 31
2,250 pounds of cotton seed meal	34.23
574.1-7 weeks pasture	143 54
Pigs, $51.00	
Middlings, 3,410 pounds $21.89	72 89
Service of bull	25.00
	$3,050 06
Profit	277.58
	$3,327.64



THE GRADE HERD.—CR.

By calves sold, 2,272 pounds	$ 100.22
Pigs sold, 3,665 pounds	126.51
Butter, 2,302.5 pounds	466.09
Cream, 703.69 gallons	428.56
Milk, 75,414.1 pounds	789 89
Skim milk, 43,465 pounds	65.20
Three cows sold during the year	103.27
Excess of receipts over expenses in September, 1897	16.68
Inventory October 1st, 1898	1,231 14
	$3,327.64

Owing to the variation in prices of the feeds bought I cannot give a stated price per ton.

This net profit is not the only benefit accruing to the farm from the herd. The manure hauled from the barn was weighed on several successive days. The average weight was 1,600 pounds, indicating a gross yield for the winter months alone of one hundred and fifty tons.

Turning to the yields of individual cows we note that throwing out the cow hurt at the beginning of the record and giving us milk for but a few days only, and the cow

Always Use the BEST.

The temptation to try a cheaper article in manufacturing high grade goods is such that the experiment is often undertaken and results generally in producing an inferior article.

High grade butter needs the best of appliances and skill and particularly the best Color.

SEARS, ROEBUCK & CO., CHICAGO, ILL.

slaughtered because tuberculous, the average yield per cow, for the year was 7,009 pounds of milk, and 304.89 pounds of estimated butter, the yield of fat being on the average 259.91 pounds. The largest yield was given by a cow evidently tracing to some Holstein ancestor. It was 10,310 pounds of milk and 344.14 pounds of fat, in forty-four weeks, the period of lactation being incomplete at the close of the year. Another cow had 9,135.5 pounds of milk to her credit, although her yield of fat is not up to that of four other cows each of which gave over three hundred pounds of fat in the year. One cow gave, in her full milking period of sixty-three weeks, 451.25 pounds of fat.

The significant lesson which the history of this herd teaches me is that while, as far as breeding is concerned, the herd is no better than dozens of others in the state, their yield of milk and butter is far larger than the average and this superiority is due, practically, entirely to continuous good care and continuous full feeding. Not that breeding is to be neglected, nor proper selection of cows dispensed with, but the farmer need not wait until all his cows conform to a given type or belong to a given breed before hoping to get adequate returns from the money invested in good feed and care.

It seems probable too that the chief fault, if faults can be compared, with the average dairyman, lies rather in insufficient feeding than in poor selection of his cows, for I insist that from the way these cows were picked up, one here and another there, wherever cows were offered for sale, they could not have been better than the average cows of the country. If all the estimates about the poor returns from the average cow be true, if it be true that the average cow gives but three thousand pounds of milk and scarcely over two hundred pounds of butter per year, and it be admitted that the cows of our herd are but average cows, then to what a conclusion does the work of our herd point as to the value of continuous, even, good care? No extra skill in the management of this herd is claimed; nothing was fed that was out of the possibility of the ordinary farmer, nor were results reached that he can not hope to duplicate.

Five hundred pounds of butter per cow per year is not a goal to breed up to, but a goal that he may start from and breed up to far better performers.

C. D. SMITH, Director.
Michigan Agricultural College.

Increasing Fat in Milk by Feeding.

ED. HOARD'S DAIRYMAN:—At every farmer's institute and dairy convention I have attended this winter, the following question has been asked: Can you affect or change the butter fat in milk by feeding? Various have been the replies which seem to have resulted from differences of opinion, and yet I have not heard any definite answer.

Nearly all milk producers know that the fat varies and the question is, it not feed, what does cause it? E. J. W. D.

Downers Grove, Ill.

The DAIRYMAN has frequently in the past stated the fact, that careful experimenters have been unable, by any method of feeding, or combination of feeds, to make a permanent increase in the per cent of fat present in the milk.

This has been the universal experience where careful and systematic feeding and milk testing have been done. The number of these tests is large and constantly increasing and they all point to the same result.

On the other hand, there are numerous dairymen, who without taking any pains to weigh food, and weigh and test milk, are convinced that they can easily change the composition of the milk. It is a question of exact science against inexact guessing, and our correspondent can judge for himself which side is the most liable to be correct. The reason for such a condition may, perhaps, be best expressed in the words of Clinton D Smith, Director of Michigan Experiment Station. Speaking of the results obtained at that station, he says:

"A study of many other cows in the college herd, shows that, while by continuous, judicious feeding, we have been able to develop animals with records approaching the incredible in total annual yields, we have not succeeded in either temporarily or permanently influencing the quality of the milk.

Each cow seems constructed to yield milk of a certain composition, and by no treatment can she be made to deviate materially from that quality."

As to what causes the variation of fat in a cow's milk, from day to day, we can say briefly, that anything that affects her physical condition, will cause changes in the per cent of fat. Heat, cold, wetness, indigestion, noise, flies, pain, or sickness of any kind, and the thousand and one things that may cause a change in her nervous condition are reflected in the milk pail, often at the expense of the owner.

Transfers of Guernsey Cattle from March 1 to March 15, 1899.

STAR BOTTLE FILLER.

Pints and Quarts. No Rubber. DO YOU CATCH THE IDEA? Write for catalogue of Sanitary Dairy Apparatus and catch more ideas.
STAR MILK COOLER CO., Haddonfield, N. J.

H. C. WATSON, of Kearney, Neb., proposes to have a 1,000 cow dairy. He has lately purchased of the Iowa Agricultural College, at Ames, a car load of fine cows. The man who has the ability to multiply himself to the extent that he can manage *profitably* 1,000 cows, is and always has been, a rarity.

An Oregon Dairyman.

S. M. Douglass, proprieter of the Springfield dairy, near Eugene, keeps a careful memorandum of the yield of milk and butter from individual cows. By this method he is enabled to get rid of unprofitable milkers. Below is a sample of his work, the time noted being one year with each cow:

	Milk pounds.	*Butter pounds.*
Cow No. 177	9,224	445
Cow No. 178	6,884	443
Cow No. 68	8,206	439

Cow No. 95	6,777	374
Cow No. 91	6,167	354
Cow No. 80	5 349	356
Cow No. 50	7,561	347
Cow No. 29	7.967	357
Whole number of cows		39
Pounds of butter		11,903
Average pounds per cow		305

CONCERNING OUR ADVERTISERS.

P. J. Coggswell recently shipped to Mr. David Roberts, of Moorestown, New Jersey, a double grandson of Exile of St. Lambert, sired by Exile's Successor 42716, and by Ophi of St. Lambert 49004 (14 pounds 10½ ounces.) In ordering an "Exile" bull, Mr. Roberts writes: "The best cow in my herd, Belle of Deleware 58331, is a granddaughter of Old Exile. When she had been fresh three months, we weighed her milk for a week, during which she gave not less than 40 pounds daily, and as high as 50 pounds some days. She is due to calve in a few days, and I hope to give her a butter test."

With this experience with Exile blood, we cannot wonder that he looks for more of the same to put in his herd.

The O. Armleder Co., Cincinnati, O., report that they are having a very heavy demand for their wagons this year. Their sales f r '99 are greatly in excess of any previous year. They are selling honest wagons at honest prices. This method of doing business will bring an increase to any concern, who follows it. The people are now finding out that it pays to buy a quality of work that will give satisfaction.

Armleder wagons give the best of satisfaction, wherever sold. It will be to the interest of any wanting a wagon, to correspond with this progressive concern.

DEWEY LET US HAVE THE FIBRE.

When Admiral Dewey destroyed the Spanish Navy in Manilla Harbor there were lying in the harbor six big ships laden with Manilla fibre for the Deering Harvester Co., of Chicago. By a special order from the Navy Department Dewey was permitted to release these ships. Their cargoes reached the Deering Twine Works in Chicago in due course, and that twine will be used to bind the sheaves of this season's harvest all over the world.

Low down, broad tire wagons are all "handy", but to get a good, serviceable wagon of that kind is the question. The Havana Metal Wheel Co., of Havana, Ill., without doubt, make the best all steel wheels and steel handy wagons made in the United States, being one of the first to put on the market a low down handy wagon. They have passed beyond the experimental part.

Their wagons and wheels have been sold in every state in the Union, and have given the very best satisfaction, as they have thousands of letters, every one of which is a testimonial to that fact. No farmer should be without one of those low down, broad tire, handy wagons. Send for catalogue, and do not stop until you have one on your farm.

Everything is guaranteed to be as they represent it to be. They also make all sizes of truck wheels for farm wagons, any size, any width tire, to fit any old wagon or new.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

TOO LATE TO CURE.

About three months ago had a cow, after eating herself full, would raise her head, grunt and move backward. Doctored her for indigestion, but it did no good. She finally got so she could not get her hind quarters along, especially her left quarter. As she was stuck last fall for lucerne bloat, and appeared to be tender in that part (left side,) concluded there was an abscess which pressed against the left kidney when she was full. Made an operation by opening a triangle; everything all right. She got so bad she had to be helped up. She now appears to be getting better, but in moving her hind quarters, she drags her feet, and in setting them on the ground they appear very weak, and look as though they would double up. She walks with kind of an elephant shuffle, and stands and moves all humped up. She has a good appetite, but has become very lean, and has lost two-thirds in milk. C. J.

Utah.

ANSWER.

You have come too late to the DAIRYMAN. You have done the business. Cow sticking for bloat, belongs to the sorry past, as well it ought. All I would give for the animal, would be the hide's value. She is not worth doctoring.

WORMS IN HEAD.—DRYING UP COW.

1st. What is the disease that causes our lambs to die? First two weeks do well, get fat, then all of a sudden won't eat; hump up throw head back, act dizzy; live about 12 to 15 hours after taken; trouble seems to be in the head.

2nd. Is it injurious to a cow's udder to lie out doors on clover and high ground during the summer nights?

3rd. Is it necessary to blanket a cow for a week after she drops calf, providing she is in a warm box stall and not used to being blanketed?

4th. One or our cows was dried up two weeks before she calved. Two weeks previous to this she was giving 30 pounds of milk a day. She dropped calf, November 17th, '98, and since has only given from 20 to 25 pounds a day. She gave 45 pounds of milk a day last year. She is a well bred Holstein, three years old. Was she injured by being milked too long?

Will she recover from those injuries?

Howell, Mich. H. R.

ANSWER.

1st. Your lambs died from worm in the brain. This is called sturdy—turnside—goggles—vertigo—gid—staggers, etc. Generally fatal; remedy quite obvious.

2nd. No.

3rd. No.

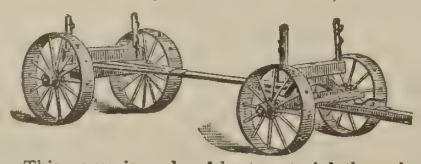
4th. She might or might not. Don't know; some are dangerously sick from not being milked; some again are injured by too close milking. Differ under different circumstances.

ITCH.

I have a three year old pure bred Jersey bull that has a breaking out on one side of neck in patches, from about the size of a quarter to a silver half dollar. To-day I found the same around the eye of a Jersey heifer. The hair comes out and leaves the skin very dry. It very much resembles sheep scab. R. M.

Poolesville, Md.

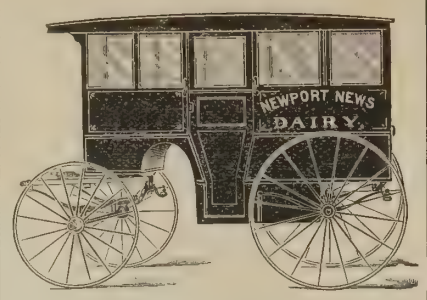
ANSWER.



You have mange, or scabies or itch, either one. They are the same. Wash in tar soap suds clean, then rewash with Tilden's Bromo Chloralum, one to eight of water; when quite dry, rub in gently, fish oil ten parts, oil of tar, two parts; rub to the very bottom. If warm weather, put in just a pinch of sublimed sulphur. Be careful of your hands or you will spread the disease.

BUNCH ON JAW.—CHANGING TO FALL COW.

We have a pure Jersey heifer calf nearly five weeks old. About a week ago, it seemed to be affected with a sort of distemper. Its nose has been running. It holds its head on one side, frequently shaking it. The calf has a good appetite and its bowels are all right, but the sickness has weakened the little animal considerably. A small swelling on the side of the lower jaw comes and goes within twelve hours. The swelling is



Farm Wagon for Only $19.95.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, sold at the low price of $19 95. The wagon is only 25 inches high, fitted with 24 and 30 inch wheels with a 4 inch tire.

This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Co., Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairymen at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,

In Stark A Grain Bags	2.70	per Ton.

Farmers may combine and order together.

Loaded on cars at our Mills at Grand Rapids, Michigan. Fifteen tons the least that can be shipped. Special Freight by Car Ferry to Milwaukee of **Five Cents per 100 pounds.**

Our large stock enables to ship promptly. Cash must accompany order.

MICHIGAN & OHIO PLASTER CO.,
401 Pythian Temple. Grand Rapids, Mich.

about the thickness and length of a man's forefinger.

We also have a heifer due to freshen July 1st. I wish to make her a fall cow. Would you advise me to keep her from the bull as long as December 1st, or would she be too hard to get with calf? W. T. S.
Lincoln, Va.

ANSWER.

I have no idea what the cause can be, if not an accident. Rub with strong camphorated spirits six parts, common turpentine two—only—parts. Rub once a day for a few days. If this does not reduce, paint over the swelling with strong tincture of iodine, once a day for a while, three to five days.

As to the heifer, you can keep her off until December if you are so inclined. Sometimes long deferred service does interfere with the breeding. Still, it is a common practice to hold them off for a purpose.

INJURY TO TEAT.

I have two cows that got their hind teat bruised, or what it may be. The teat is somewhat shrunken, or thinner at the lower half of the teat. I get milk out of them, but it comes only in a very thin stream and with pain to her. I think the cows must have stepped on it themselves by getting up, as there was a little white spot at the end of the teat. There is no inflammation in them. I greased them but it did not improve it.
Lancaster Co., Neb. H. T.

ANSWER.

By using the best and easiest milk tube and dilating plugs. See ads in DAIRYMAN.

It is a matter quite impossible for me to say how or when the teats were injured. It might be from frost. Rub in fish oil and lard, 2 ounces each; pure alcohol, 4 ounces, to be thoroughly mixed. Rub twice a day for a few days. Must have the tubes and plugs to be successful.

ITCH.

I have a cow that has a white scab around one eye. It commenced with just a little spot, but now it has grown so it is around the whole eye. It is hard and white and seems to get larger and larger. W. J. M.
Westby, Wis.

ANSWER.

Scabies, itch, mange, and other forms of disease of the cuticle quite often center around the eyes. Wash with Tilden's Bromo Chloralum one to eight parts of cold water. Let this be well applied four to six different times. Then dress with oil of tar one dram, pure clean lard twelve drams, to be well mixed. Put one dram of sublimed sulphur in this. Thoroughly mix.

INFLAMMATION OF OVARIES.

A neighbor had a Jersey cow die with the following symptoms: constipation, fever, eye staring, apparently mad, straining, apparently in heat for 4 days and nights, bellowing repeatedly till she died. Fed clover hay, corn chop and bran. T. A.
Dodson, Mo.

ANSWER.

Inflammation of the ovaries, causes numerous. In this case I am quite unable to form any idea of the cause. In extreme sexual irritation and excitment I have known and seen such subjects go raving mad before relieved by death.

SCROFULA.

A neighbor has a cow that has been ailing all winter, off feed. Of late swellings have come under jaw and on brisket, and almost all over body; in a few days has two more break out with swellings on body from nose to tail, but on different parts. C. H., Jr.
Lykers, Mont. Co., N. Y.

ANSWER.

I don't believe the cow is worth doctoring. She appears to be thoroughly impregnated with scrofula. I would not use the milk from such a subject, nor would I attempt to breed from such a contaminated animal. Let some good veterinarian see and examine her.

WART ON TEAT.

I have a two-year-old heifer that has a wart on one of its teats, about the size of a half of a peanut. The heifer will calve in about two months. P. T.
Marinette, Wis.

ANSWER.

Touch all the wart with butter of antimony, morning and evening, for two days; then change to nitric acid two days; then the butter of antimony for the same, if needed, only keep the acids from touching any other portion of the teat. Use a small piece of pencil sized stick and cotton batting, tied tightly to the end, kept clean. Rub the wart a little each time. You must change the cotton batting each day, as the acid eats it too tender, and it will not perform the job.

POOR FLOW OF MILK.

I would like to know what to do for a cow that came in one week ago to-day. I have not been able to get more than one pint to one quart of milk to a milking, milk has some chunks in it, did not get her entirely dry before she came in. H. A. C.
Pompey, N. Y.

ANSWER.

Immediate full dose of physic and repeat in 4 or 5 days; each morning give 2 teaspoonfuls of nitre. Do this for 10 to 20 days, if needed. Stop the corn for a little while and put in more oats and bran, make this sloppy, and give new milk warm for a while; give 2 drams of fluid extract of blue flag in 3 oz. of old whiskey and 5 of water. This is to be apart from the physic, give as soon as the physic is over. There are all sorts of freaks regarding the milking qualities of cows, which no man, but a layman, can account for, only upon the peculiar idiosyncrasy of the subject.

HYDROCEPHALUS.

On the morning of March 25th, I noticed one of my full blooded Jersey heifer calves two months old, acting droopy and refusing to come to the bucket for its morning milk. It lay around all day very droopy; at 6 p. m. it got up and commenced running around, getting faster all the time, running against the picket fence so hard as to break the pickets, then running against the side of barn, almost breaking the barn boards. At 7 p. m. it fell and kept its legs moving, same as it would if still running but in a few moments was dead. A. F. P.
Topeka, Kans.

ANSWER.

You had a clear case of hydrocephalus, water on the brain. Cure not worth attempting as the disease is fatal in 90 per cent of cases in calves.

CALF DISEASE.

We lost a calf the other day which seemed to be almost bloated. It was fed about half milk and half water and oil meal, cooked, was added to the milk, besides getting ensilage, ground feed, corn and oats and hay. The calf was three months old.

We had another calf fed just like her, and she seemed to become the same way as the one that died. But we gave her, immediately, Epsom salts and ground ginger, which has made her scour now. But she seems to be quite full yet in her belly, as though she was bloated a little. K. AND W.

ANSWER.

Ensilage is not a calf food. Epsom salts as per head of this column, is the calf and cow physic—not pills of any kind. I believe the cause to be the silage.

WEAKNESS IN CALVES FEET.

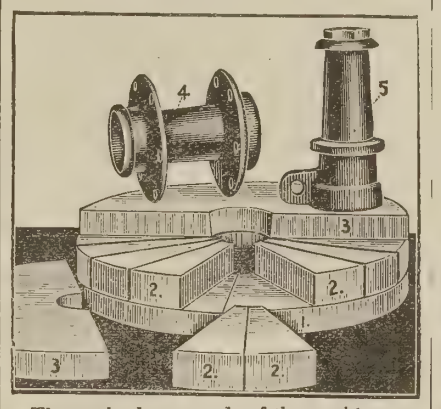
I have a choicely bred Jersey calf that is 12 days old. Has seemed hearty up to this time and took her milk promptly. I have been putting a handful of corn meal into pail with the milk, for a few days, which she licked up and enjoyed, but as it seemed to physic her, I dropped it and have been feeding twelve-hour-old milk with cream removed (as we are rather short of whole milk). Tonight I noticed that her hind feet are turned back under her and she walks on her ankles.

I have another 5 days older, that I have been feeding just the same. She too was physicked in the same manner by the meal, so I quit feeding at the same time I did the other but she is all right. J. M.
Serena, Ill.

ANSWER.

Bandage the joints or use splints for a while, removing them intelligently once in a while. Soak the bandage in strong oak bark solution, tea. To each pint add 2 ozs. of acetic acid. Keep the bandages soaked in the solution.

GARGET.



One of my cows came fresh in May, all right, and in good shape, but in November she commenced to have garget in one half of her udder, and I bathed it with salt water and gave her saltpetre; but she got worse, and I dried her up January 1st. After three months the swelling is coming back again, and is inflamed. She will be fresh in six weeks. J. J. S.
Winneconne, Wis.

ANSWER.

Full and continued physicking. Rub the gargety parts with strong tincture of camphor, six parts, and common turpentine one only part. Rub hard and long once a day for awhile, say four to six days; then use pure lard and alcohol, half and half; rub in well. One of the best things for chronic garget is massage, persisently followed up by kneading and squeezing, and gently rubbing, etc. The continued physicking is the sheet anchor. You may give, apart from the physic, two drams of poke root once a day, every other day up to four doses, and you may rub the fluid extract upon the udder, also.

ILLUSTRATION.

There are three old and true sayings, viz.: that a chain is not stronger than its weakest link, and that the life of a wagon is gauged by the durability of its wheels. This being true it is wise for any farmer to look to the durability of the wheels on any wagon he proposes to buy, and as there is nothing but what may be injured, it is well to keep in mind the ease with which a wheel can be repaired. There has probably never been a more durable wheel made than the one shown in this cut.

These wheels are made of thoroughly seasoned white oak, dressed on both sides and edges. The pieces marked No. 1 are keyed tightly together and then the wedges or spokes (No. 2) are fitted in. These wedges are all cut with the grain running lengthwise, and form a solid series of spokes from the iron hub (No. 4 to steel tire not shown). After the last wedge is driven in tight, the planks marked No. 3 are placed on top with the grain running crosswise of the grain in layer marked No. 1. The wheel is thoroughly bolted by ten bolts, which pass through all three layers. The hub (No. 4) and skein (No. 5) are made from high grade Lake Superior iron with smooth wearing surfaces. The box is made with a wide flange on each end, and these fit up on each side of the wheel and are drawn up tight to it by bolts which reach through the wheel from one flange to the other. There is a wide sand band on each end of the box to keep the sand out.

The tires are made of steel, and are given a draft that would crush any open spoke wheel.

After the foregoing description we need say nothing more about the strength and durability of these wheels. Neither arid nor wet climes have any effect on them, as the grain of white oak cannot shrink endwise. When the tires are shrunk on, the end grain of the middle layer cannot be compressed, and the tire therefore has a slight crown in the center: and to slip off either way the tire would have to climb this ridge. It is absolutely impossible to start these tires with blows from the heaviest sledge.

The patents on these wheels are owned by The Farmers Handy Wagon Co, of Saginaw, Michigan, and are used only on their famous farm trucks.

THE LAWRENCE-WILLIAMS CO., Cleveland O.

Southeastern New York Farm Notes.

Milk Trusts and Milk Shippers.

ED. HOARD'S DAIRYMAN:—As a matter of news, those who are acquainted with the history of the "Five States Milk Producers' Association,"—an association of milk shippers that supply New York City with milk—will wish to know what was accomplished at the recent meeting in New York city. Before this the milk dealers and the officers of the F. S. M. P. A. were unable to make a contract for the reason that the latter could not guarantee a definite amount of milk. The milk shippers were then induced to sign a contract in which they gave their officers the powers of attorney in the disposal of the milk.

The latest report is, that the expected contract between the F. S. M. P. A. and a New York syndicate of milk dealers, has failed. The attorneys of the Consolidated Milk Company, the name of the syndicate that was to purchase the milk, informing the committee of the F. S. M. P. A that under the laws of New Jersey the trust or combination could not be formed, because the powers of attorney claimed and included in its provisions had no reality. The committee at once offered to buy shipping stations along the routes to overcome the difficulty, but the proposition was rejected.

As the matter now stands, it places many farmers who signed the powers of attorney in a dilemma, for they do not know what to do with the milk. In my locality, there are several condenseries that make contracts for milk the first of April. The farmers who signed the powers of attorney were unable to make contracts with the condenseries, and they must now make the best disposal of their milk possible.

THE MILK SHIPPERS' SITUATION.

In Southeast New York, the most of the farmers either ship their milk direct to New York, or deliver their milk to creameries that ship milk and cream. The farmers have been so long established in this custom, that they think they can do nothing else but sell milk. In the last few years, the production of milk has been so large that in the summer the price has fallen to about one cent per quart.

This is but little more than the cost of production. Few farmers have the facilities and the ability for making the kind of butter the market demands. The farmer who takes his milk to the butter factory and pays for making and marketing it, realizes but little more than the milk shipper. Only the few well-to-do farmers are making a good living. The majority are either making a very meagre living, or are going behind.

It is evident that something must be done to widen the margin of profit, or the milk shippers cannot make a living. Selling milk has not been a way to better farming in this locality, but rather the cause of its decline. Too much of the farmer's time has been occupied in delivering his milk to the milk station or creamery, and drawing grain from the feed stores. The farmers must now face the fact that they are coming to a place where a new order of things must be put in opperation.

THE PROBLEMS TO BE WORKED OUT.

There are two problems with which the milk producers have to deal—cheaper distribution and cheaper production. The former means reducing the profits of the middle men, and the latter a better system of farming. To increase the price that the producer gets for his product when there is a surplus, is always difficult, but it will be understood that the purpose of the F. S. M. P. A. is not to make the consumer pay more for the milk, but to obtain for the farmer a reasonable part of the money the consumer pays.

Much of the milk that the farmer gets but 1 or 2 cents per quart for, is retailed in the city for 6 to 8 cents per quart. If the F. S. M. P. A. may be called a trust, it, unlike other trusts, does not seek to make the consumer pay more for the product to enrich a few individuals, but rather to furnish the consumer better milk at a less price, and thereby increase the consumption, to take care of whatever surplus there may be, and to give the farmer his share of the price of his milk, when that price is regulated by the law of supply and demand.

The F. S. M. P. A. has succeeded in a very difficult undertaking, that of uniting a large number of farmers, and this recent instance of a failure to make a contract with a combination of milk dealers is not an evidence that it will not accomplish its purpose. The facts are, the farmers are compelled to unite, and demand a better price of the middlemen, but not from the consumers.

While this problem of a more economical distribution of dairy products is being worked out, the one of cheaper production should also be studied. We must expect low prices in the future. No combination or legislature can save the producer from the natural results of large production and increasing competition. There is no possible way to maintain prices for a very long time above those which are made by the supply and demand.

As long as so much milk is produced the price will be low, and the only way to make a living profit with low prices is to institute better methods of farming. In a word, the majority of farmers need converting, that they may adapt their farming to suit the times. The means of their salvation are better cows, soiling crops, or to stop buying so much grain, and growing the food on the farm, and saving carefully all the manure that they may enrich and build up their farms.

Delaware Co, N. Y. W. J.

One Hundred Per Cent Gain.

A Texas Dairy—Texas Weather—Texas Feeding.

ED. HOARD'S DAIRYMAN:—Below I give the ration we are feeding and I wish you would comment on same and tell us what improvement could be made. We are milking twenty-two cows (a majority have been milking for six months) and are making twenty pounds of butter per day.

We are feeding 4 quarts bran, 4 quarts corn meal and 6 quarts cotton seed per cow a day. Some that are nearly dry don't get this amount. Bran is worth $16 per ton, corn 35 cents per bushel, (we grind it ourselves), cotton seed $7 per ton. We have about eight tons on hand. I know you do not favor cotton seed, except in small amounts.

We have had the coldest winter in forty years, so the old inhabitants say. Cold weather is not welcomed by us, though HOARD'S DAIRYMAN always is.

We have been running a dairy four years. When we commemced could not make a half pound per cow, but HOARD'S DAIRYMAN showed us the way. Of course it is far ahead of us now, but we have it in sight and are still following. C. M. R.

Elmendorf, Texas.

We cannot judge as to the elements in a ration without knowing the weights of its several constituents. We can estimate fairly well as to some kinds of grain, but bran is very variable, and cotton seed we are unacquainted with. But a ration that produces good results must be a good ration. We account the yield reported very satisfactory, and if the amount of cotton seed fed does not affect the quality of the butter unfavorably, there is no reason for discarding it, either in whole or in part. We aim to be reasonable in all things, and when we are without personal experience, must be guided by the experience of others. Several of the experiment stations in the South have studied the cotton seed question very thoroughly, and all agree that while it furnishes, in whole seed, meal and hulls, a valuable and cheap addition to the ration, it needs to be fed with care and not to excess. Three pounds of the meal is accounted the maximum limit where butter is made, and less is recommended as the general rule. For the whole seed four to five pounds per day is as much as should be fed, and we think even less than this would tend to an improvement of the product.

The Value of Dairying to a Community and State.

The Views of an Eastern Man Expressed in Oregon.

The *Oregonian*, the leading paper on the Pacific coast, prints the following forcible presentation of the dairy question in its relation to the prosperity of the state:

"You people out here don't realize the importance of your dairying industries," said a man from Wisconsin yesterday, as he leaned back in a hotel chair.

"Why, back where I came from, the dairymen would be rolling in wealth, every one of them, if they had your advantages in the way of mild climate, abundance of grass, etc. Of course they have the benefit of larger markets there, but I am sure the dairymen of Oregon and Washington will never lack for a good market as long as it is necessary to import dairy products from the East to supply the local demand.

The point is just this: Increase the output of your dairies, not by adding more cows, but by replacing ordinary 'scrub' cows with those breeds which experience has shown to be best adapted to the particular line of dairying in which you may be engaged. These dairymen's institutions should be held oftener, and should have the attendance of every man engaged in the business. The time when a man can afford to drivel along in the same way his father did, is past. He must make a study of his business, and must profit, not alone from his own experience, but from the combined experience of the most successful men in it. The value of this is recognized in the East, but out here they seem slow, very slow, to take advantage of opportunities afforded them. I attended the association meetings, and was highly pleased to hear some of Oregon's leading dairymen speak; but the need is not for a few well-informed leaders, but for a universal information reaching all. Of course, the leaders come first, and without them there is no progress, but the people should not be content to be led all the time.

"You boast of your mineral resources, of your bodies of timber, and great fields of wheat, but you pay little attention to the development of your dairies. Within them lies the richest resouce of all, the one most easily within the reach of the poor man. When these great farms, whose acres are numbered by the hundreds, shall have been replaced by small tracts that are farmed from center to circumference; when every tillable acre is under cultivation, yielding the largest crops that skilled and systematic labor will produce; then you will see the truth of my criticism, and wonder why in the early days of 1899 the farmer did not grasp the importance of dairying, rightly conducted."

RETURNING YOUTH.

"I am seventy years young," said Oliver Wendel Holmes when they asked his age. True enough. He was young because his heart was young; his step was firm; his eye was bright; his laugh was clear and merry; his appetite was good, and above all — so was his digestion.

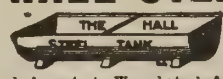
No man should be old before his time because of a weak stomach, sluggish liver, shaky nerves and flabby muscles. There is no need of it. Dr. Pierce's Golden Medical Discovery cures these things. It brings back youth to the feeble because it brings back keen appetite and good digestion. It tones up the liver, puts oxygen and life into the blood, and solid strength into the flesh and muscles. It contains no alcohol to inebriate or create a morbid appetite or craving for stimulants.

"I have never felt better in my life than I do now," says Charles Hunwick, of Lenox, Macomb Co., Mich., in a remarkable letter to Dr. R. V. Pierce, of Buffalo, N. Y. "I have taken Dr. Pierce's Golden Medical Discovery right along. I can now walk quite well with a cane and hope to throw even that away before long, and as I have had to use crutches for nearly two years, I think I am doing fine. I do not cough now and I can eat and sleep like a school boy. I think I will have to change my mind about 'Patent Medicines,' as I never had much faith in them; but you must know that I have been treated in two hospitals and by three doctors besides, and received no benefit; so I think your medicine is the only medicine for me."

There is nothing in the world for constipation like Dr. Pierce's Pleasant Pellets. They should be taken in conjunction with the "Discovery," whenever any disease is complicated with that dangerous condition. Nothing else that may be offered in their place will accomplish what they will. And their relief is permanent. Write to Dr. Pierce for free advice.

PARSNIP COMPLEXION.

A majority of the ills afflicting people today can be traced to kidney trouble. It prevades all classes of society, in all climates, regardless of age, sex or condition.

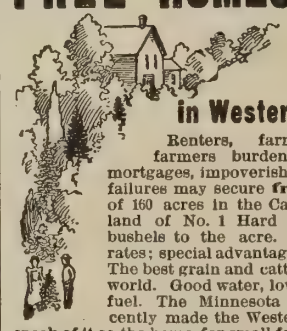


The sallow, colorless-looking people you often meet are afflicted with "kidney complexion." Their kidneys are turning to a parsnip color, so is their complexion. They may suffer from indigestion, bloating, sleeplessness, uric acid, gravel, dropsy, rheumatism, catarrh of the bladder, or irregular heart. You may depend upon it, the cause is weak, unhealthy kidneys.

Women as well as men are made miserable with kidney and bladder trouble and both need the same remedy. Dr. Kilmer's Swamp-Root, the great kidney, liver and bladder remedy, will build up and strengthen weak and unhealthy kidneys, purify the diseased, kidney-poisoned blood, clear the complexion and soon help the sufferer to better health.

The mild and extraordinary effect of Swamp-Root is soon realized. It stands the highest for its wonderful cures of the most distressing cases, such as weak kidneys, catarrh of the bladder, gravel, rheumatism and Bright's Disease, which is the worst form of kidney trouble. It is sold by druggists, in fifty cent and dollar sizes. You may have a sample bottle by mail free, also pamphlet telling all about it. Address Dr. Kilmer & Co., Binghampton, N. Y.

When writing please mention reading this generous offer in HOARD'S DAIRYMAN.



HALL STEEL TANKS

are the best for supplying water for live stock. Being made of galvanized steel they cannot rust, rot, burst from freezing, fall to pieces from drying out, etc. We make tanks for all purposes. Also troughs for feeding calves and pigs, cooling milk, hauling liquid manure, etc. Write for what you want. We will make it. Special price to *first inquiries* from *new territory*. Circulars and price list mailed free.

64 N. Ashland Ave. CHICAGO, ILL

FREE HOMESTEADS

in Western Canada.

Renters, farmers' sons and farmers burdened with taxes, mortgages, impoverished soil and crop failures may secure free homesteads of 160 acres in the Canadian West, the land of No. 1 Hard Wheat, 25 to 35 bushels to the acre. Lowest railroad rates; special advantages to prospectors. The best grain and cattle country in the world. Good water, low taxes, abundant fuel. The Minnesota editors, who recently made the Western Canada trip, speak of it as the home for small farmers. The official report says: "To the small farmer seeking a new home Western Canada offers great inducements. While it seems a long way north the Canadian Pacific Railway line is far south of Edinburgh, the climate is that of Northern Minnesota, and the land raises splendid and sure crops."

For maps and full information apply to Supt. Immigration, Ottawa, Canada or to

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY. Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premum.

or

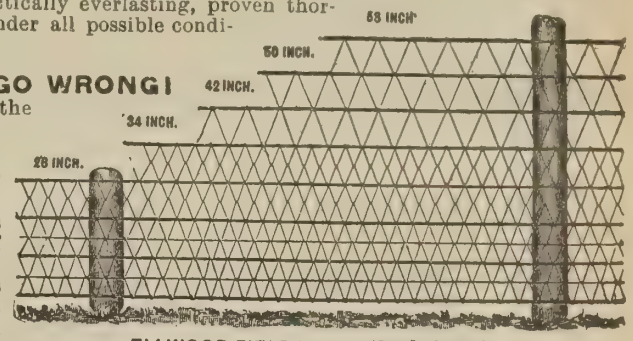
Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehenisve from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.



IF YOUR PASTURES AND FIELDS ARE INCLOSED WITH THE

ELLWOOD ALL STEEL WOVEN WIRE FENCE

THE SHARPLES TUBULAR CREAM SEPARATOR.

The bowl alone revolves.
It spins on air.
It is a hollow bowl.
It is a simple bowl.
It weighs but 30 pounds.
It skims two tons per hour from .05 to nothing.

This is the first Tubular ever sold and has been running over one year and not a cent for repairs.

P. M. SHARPLES,
West Chester, Pa.

FRANKVILLE, ONT.

Dear Sir :—Your Tubular Separator, which we are using in our factory is skimming over 4,000 lbs. of milk per hour, and to-day we skimmed 6,000 lbs. of milk in eighty-five minutes, and did not leave a trace of fat in the skim milk. The cream produced is the smoothest and finest in quality we have ever seen from any separator. When the separation is completed the bowl can be washed in a few minutes, and it is simply a hollow bowl with no corners or tubes. No other separator compares with it in efficiency, and our large experience leads us to believe it will never have an equal.

JONES & RABB.

An average from 73 tests of skim milk of					.034 of 1%

IN THE FACTORY.
The U. S. Takes the Cake.

POYNETTE, WIS., Jan. 20th, 1899.

Have been running U. S. Separators since 1892, and can cheerfully say that the new No. 1 Improved U. S. Separator takes the cake. When the skim milk is tested it shows only a trace of fat. I won the sweepstakes and three other first prizes, amounting in value altogether to $115.00, at the 1898 Wisconsin State Dairymen's Association, and all because my No. 1 U. S. Separator makes such smooth, perfect cream.

R. M. BUSSARD, Prop. Bussard's Creamery.

AND IN THE DAIRY.
Very Durable, Very Easy to Operate, Never Out of Order.

TIFFIN, OHIO, Nov. 28th, 1898.

Have used the No. 5 Improved U. S. Separator nearly three years and do not think it is worn a particle. It runs as smooth as the day we first started it. **It is the best separator in the world,** it is so easily run and so easy to clean, and it is always in order to do the best of work. We wonder how we ever got along without one. We think very much of the enclosed gearing. You have the best machine I know of in running and mechanical construction.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

NOW IS THE TIME TO PREPARE.

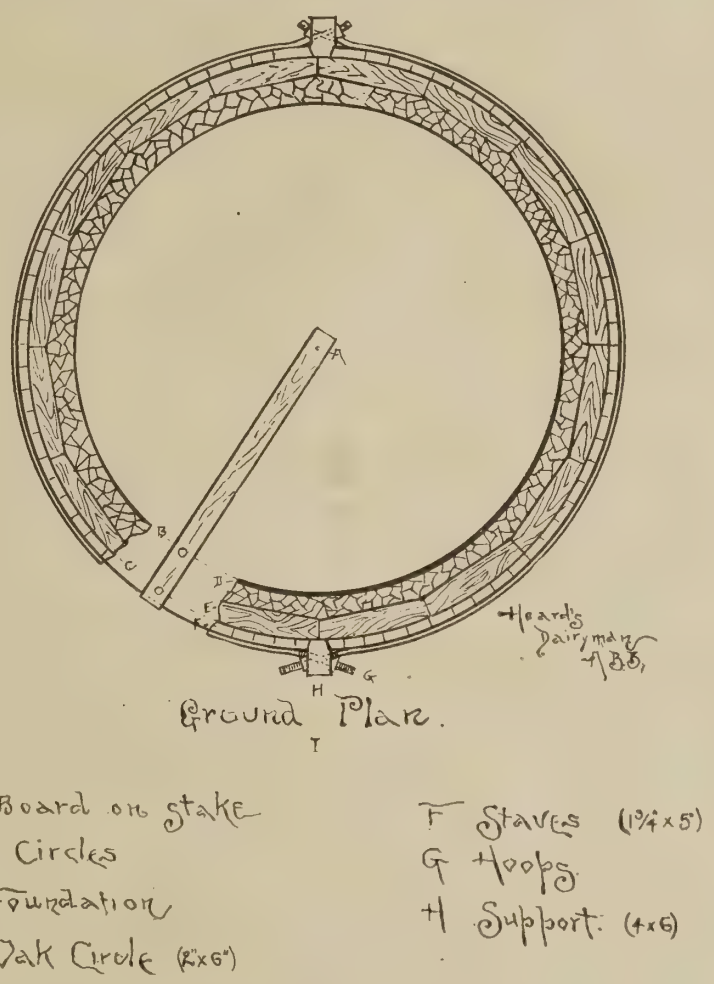
There is no denying that a great many dairy farmers will not buy bran, oil meal, cotton seed meal or gluten meal, as long as the prices remain as high as they are at present. What makes the prices high is the fact that there are enough other farmers, both in this and foreign countries, who will buy these protein feeds. But that does not help out the first class. They grow an abundance of corn, oats and timothy hay, but those are carbonaceous foods. What they lack is the very protein that is found in the by-products they must purchase. Even if they are convinced that it would pay to sell some of their corn and oats, and buy bran, oil meal, cotton seed meal or gluten, the fact remains that they are very loth to exchange their grain at low prices for the other products at high prices.

Hoard's Dairyman, a number of years ago, started the cry about growing the Canada field peas, as a substitute for those costly protein feeds one must buy. We have never since seen occasion to regret our work in that particular.

Now is the time, however, to act on this matter, if we are to sow peas. Select a high, dry piece of ground, one that can be worked the earliest possible in the spring. It should also be of good fertility, and stubble or last year's corn ground is preferred to sod. As soon as practicable, either plow or disk it thoroughly; harrow once and sow on two bushels of the small Canada field peas. Then plow them under *not less than four inches deep*. Harrow once, and let lie for about a week; then sow a bushel and a half of the White Schonen oats, or some other of the stiff strawed variety of oats, and harrow in well. By sowing early, we get ahead of the hot, dry weather in July, and the peas fruit more abundantly. If they are wanted for hay, cut just as the peas have passed well out of the boiling stage. Cure in the cock with hay caps.

If the grain is wanted, be sure to cut rather green, before the pods will open and shell. It is better to cut too early than too late. Thresh in the loose straw and grind the oats and peas together. This constitutes a rather heavy feed, and each farmer should experiment on his cows to know just how much each individual can take safely and respond at the pail. The oat and pea straw is nearly as valuable as clover hay, and it will be found that cows will relish it well if it is kept bright and sweet.

In this way the farmer can provide himself with an abundance of desirable protein food.



To help in the same direction, he should grow an abundance of clover, for clover and alfalfa are among the richest of the protein coarse fodders.

By all means try the experiment of sowing a patch of alfalfa this spring, if it be no more than an acre. Look into the matter and study it well, for it will pay any milk producer to give it study and patient experiment.

There are altogether too many farmers succeeding with alfalfa from Massachusetts to Oregon, to dismiss it with a half thought, and it is one of the finest milk feeds in the world.

BUILDING A STAVE SILO.

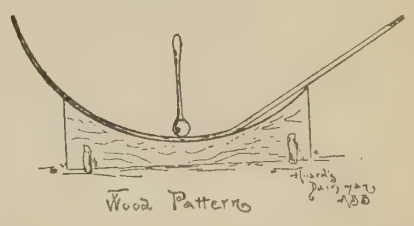
Many of our new subscribers are asking for information as to the methods and material for building a stave silo. For their benefit we reproduce cuts and description of the Purdue University Silo.

Attention is specially called to the use of wire fencing for an elastic hoop, as described by John Gould, in the last volume of the Dairyman. This was not used in the university silo, but as the suggestion seems to be exceedingly valuable, as a method of keeping the silo staves in place when the silo is empty, we include it in the description.

Laying Out.—In the center of the silo, a stake was driven and sawed off at the height the foundation was wanted—in this instance, three inches above the ground.

On top of the stake, one end of a board was held by a nail. Five feet, ten inches from the nail a hole was bored, and 14 inches farther a second one. With a sharp stick two circles b and c were marked on the ground. The space between was dug out 2 feet deep for the foundation.

Foundation.—Small stones were used for the grouting underground; a layer of them was placed in the bottom of the ditch, then mortar made of one part lime, two parts Louisville cement and nine parts fine gravel was poured in and distributed with a hoe; after that a second layer of stones put in place, care being taken to have them rest firmly in place. This alternating process continued till level with the ground. For the top few inches below the ground Portland cement and no lime was used. Above ground, which was sloping, the wall was three inches high on one side, and 18 inches on the lower side. Large stones laid (in Portland cement and sand one to three) by a mason completed the foundation (d). On it an oak circle (e) (of 2 inches by 6 inches) was bedded in cement. It was made of one inch stuff cut in segments of a circle. These sections, breaking joints, were nailed together, giving the desired thickness.



Staves—(f) are white pine, dressed on two sides; and edges beveled 1-16 inch, leaving the finished stave a scant 1¾ inch by 5 inches. Twelve and 16 foot pieces make the desired height of 28 feet, breaking joints when put up. In the end of the stave at joint is a galvanized iron strip 2x5 inches. Notches for these sawed at the mill.

Hoops.—(g) Ten in number, of ⅝ round iron, with ¾ inch ends threaded 8 inches, threaded ¾ inch lugs welded on to the ⅝ rods. Cost $1.00 per hoop. Each hoop in two pieces to facilitate tightening. As a support for the hoops (h) when not tight, a 4x6 was substituted for a stave on opposite sides of the silo. Through the projecting portion holes are bored for the ends of the hoops, making both a support and tightener. The hoops should have the same curve as the foundation. It may be secured by a plank sawed to the proper curve, lay on hoop and bend with a maul, used like an old churn dasher, straight up and down.

In place of solid iron hoops, it has been suggested to use a band of 52-inch wire fencing cut of sufficient length, so that each end is wrapped about a 4x4 inch oak scantling, and that when put round the silo the end pieces will come within about ten inches of each other and are tied together with two one-inch bolts with double burrs. The "pull" of this band is simply immense, and the coil of the wire takes up all slack, when the silo shrinks when empty; and expands when the staves swell, so pull all of the time. The bands are placed far enough apart, so that three man-holes are sawed in between the bands.

Erection—(f) The 12 foot 4x6 first put in place, plumbed and braced securely by board nailed to a stake. The braces so placed as to leave one side clear to work on. The top and bottom hoops put in place and the center supported temporarily by a stave. After tarring the ends and edges of the staves, they are placed in position and held by a nail driven just under or over the hoop and bent around it. This hoop was firm enough to lean a ladder against; 12s and 16s were put up alternately, till the space was full, then that side drawn up. Similarily the other half was put up.

Pieces resting on the 12s and between the 16s made a scaffolding on which to work. The 16 feet 4x6 was placed against the silo with the upper end resting between the same staves as the twelve feet. A hoop was put in next the top hole, then two men at each timber raised them, hoop and all, up to their place. A brace to the barn, with one large nail at each end, allowed the pieces to be raised without tipping over. The bottom hoop for the top timber was now put in, but not drawn tight. The staves were now put

up, a 12 foot on a 16 and a 16 on a 12 and fastened to the upper hoop same as the lower ends, using a ladder leaned against the hoop and standing on the scaffold. It was found more convenient to put the strip of iron in the bottom of the top stave and then guide it to the place in the top of the bottom stave. It would be less trouble to build a scaffolding inside the silo, which would not have to be moved to make room for the upper stave.

When putting in these upper staves, the top hoop of the bottom section must not be tight or the upper staves cannot be crowded into place.

Tightening.—After all the staves were in place and the four hoops drawn tight enough to hold them securely, the remaining hoops were put on. With one man on a ladder inside to drive back any stave which was too far in, another one tightened up the hoops. Before drawing too tight the hoops should be moved up or down so as to be equally distant on all sides and held by large staples.

Doors.—Four are cut by sawing four staves at an angle of 45 degrees, long side of stave inside. When the place was reached where rows of doors should come, one stave was sawed nearly through in the proper place for each door, and a narrow board tacked on to prevent breaking in handling. When complete, remove board, and saw as many staves as desired for width of door.

Roof.—For the present, none will be put on.

Cost.—

Staves	$70.70
4×6 bored for hoop support	5.20
Circle for sill	3.10
Hoops (10)	10.00
Lime and cement	5.00
Mason's time	2.80
Staples and nails	.30
Total	$97.10

Returns from a Hand Separator.

Ed. Hoard's Dairyman,—I notice in your issue of March 17th, R.M. G., of Iowa, asking about hand separators. I have a De Laval Baby, No. 2, and here it is in a nut shell on herd of 10 cows:

Milk from 10 cows one year 70,000 lbs.	
Cost of hauling when hired at 10c per cwt.	$ 70.00
Cost of separating at creamery	40.00
Total	$110.00
Cost of separator	125.00
Only lacking	$ 15.00

Of paying for machine in one year, and so far as I can see the machine is good as ever.

If I had to haul the milk myself, the figures would be as follows:

Cost of hired man at $15 per month for 10 months	$150.00
Cost of separating	40.00
Total	$190.00
Cost of separator	125.00
Balance in favor of hand separator	$65.00

Then there is hired man's board which I have not counted; and again, I have my milk always warm and sweet, when feeding time comes.

Taking everything into consideration I think it foolishness for any creamery patron living more than one mile from creamery, to do without a hand separator. M. L. D

Edgerton, Kansas.

HAULING MILK TO THE FACTORY AND CREAMERY.

One of the most expensive parts of the creamery business is that of getting the milk to the central manufacturing point. Everyone recognizes its great expense, but in that, as in many other things, we are bound by custom. One of the methods taken to reduce this expense was related in a farm institute by Mr. M. A. Brown, the well known creameryman, of Rockford, Illinois. He stated that on one of his milk routes, eight farmers united in taking turns, in carrying the milk to the creamery. They kept a special rack, for hauling, with springs, which saved the jamming of the cans. This rack was left every night at the farm of the patron farthest from the creamery. Whosoever turn it was to carry the milk drove to this farm with his own rig. By this system it cost five cents per 100 pounds to deliver the milk.

ALFALFA BUTTER.

The history of dairying in the United States, if it could be written, would show a constant breaking down of false standards, false hopes, false notions of what is the truth. Only a few years ago, within easy memory, it was thought there was a dairy belt in this country, where for all time pretty much all of the food, butter and cheese would be made.

Among other false notions, was the one that alfalfa would not make good butter. On that point our Pacific contemporary, the *Western Creamery*, says:

"Until 1897 it was commonly believed that alfalfa would not make good butter, but when ten California tubs of butter were sent to the National exhibit, at Owatonna, Minnesota, and alfalfa secured the highest score of the lot, it dawned upon our people that they might be mistaken. When again, at Topeka, Kansas, the alfalfa butter secured the highest score of the four tubs sent from California, an impression was made upon the trade, and with the intrinsic merit of such goods to sustain the reputation there gained, alfalfa butter has since stood in the first place in our markets."

KEEP A RECORD.

A New York farmer who has kept a record of the product of his dairy for three years past, weighing each day's milk and testing it twice a month or oftener, reports that last year the product of thirteen grade Jersey cows was 4,557 pounds of butter, which, at 20 cents a pound, gave an income of $911.40, or a fraction over $70 per cow. The best cow, 8 years old, produced 474 pounds of butter, worth $94 80. Three others produced over 400 pounds each, three others over 375 pounds, four between 300 and 350 pounds each, one 269 pounds and one 2-year-old, only 127 pounds. The ten best averaged 376 pounds each, or over $75 worth per cow. One 2-year-old made a record of 377 pounds, and one 3-year-old made 414 pounds. These are good heifers to keep, but if the two that produced less than 275 pounds do not soon get into the hands of the butcher or some one else, we shall think it strange.

By virtue of keeping a record on those cows, the owner had the chance to discriminate, intelligently, when he disposed of any of his cows. A great many farmers believe that they know well enough which are the poor cows in their herd, without going to the trouble of keeping a record which, after all, is very little trouble.

A few years ago the writer had occasion to purchase a cow. He applied to a thriving dairyman in this vicinity and was offered two cows, one a three-year-old grade Jersey for $25, and the other a large grade Short-horn for $60.

We looked over the two carefully, and asked the farmer what was the reason of his low price on the Jersey heifer. He replied, "She is all right, but she does not give milk enough." "How much does she give?" "O about 12 quarts a day." "Have you ever tested the milk?" "No! I can't fool away my time testing cows." "How much does the big Short-horn give?" "Well, she will fill a ten quart pail twice a day, and I tell you she's a good one."

We concluded to buy the heifer, much to the disgust of the farmer, who said he "thought we were a better judge of cows than that come to."

We found that it took only 15 pounds of the little cow's milk to make a pound of butter. A test of the big cow showed that it required 33 pounds to make a pound of butter. When we finally convinced the farmer that he had sold the most profitable cow in the herd for $25, *all because* he "couldn't fool away his time testing cows", he said he had received new light on the subject. His subsequent history showed that from that time he put in practice better methods of dairy management. It will pay to do it.

CAN WE IMAGINE IT?

The wonderful advance in dairy methods, in creamery and cheese factory machinery, which have come in twenty years, leaves us with but imperfect recollection of how things were managed before that time.

In 1878 at the International Dairy Fair held in New York City, the first public exhibition of a centrifugal milk separator (the Danish-Weston) was made. That marks the beginning of the era of a most wonderful progress in the mechanics of dairying. Mr. Gilbert W. Lathan, in his address before the National Butter Makers' Convention, asks this: "Can we for a moment imagine ourselves in an age where the separator is unknown, and the 732,000 cows of neighboring Iowa have their annual milk product of two billion, two hundred million pounds of milk set in shallow or deep pans, and make 90,000,000 pounds of butter, instead of 100,000,000 pounds."

This march of improvement has affected every part of this great dairy system, much more than it has the man on the farm. Yet he is the "man behind the gun" after all. Every step in the handling of milk, has been cheapened and rendered more effective, yet there are thousands of farmers who are producing milk just as expensively as ever. This should not be. The farmer should be just as keenly alive to the *economy* of better ideas and methods, as any man in the line.

He must do his part in the march of progress, or he will not get his share of the reward.

A clear idea of what we mean can be obtained in every creamery. The creamery receives so much per pound for the butter made, whether from the patron who makes a profit on his cows, or the one who makes a loss.

The one who keeps cows at a loss is usually a man who don't believe in improved cows or improved ideas. It is said in Holy Writ, "For he that hath, to him shall be given; and he that hath not, from him shall be taken even that which he hath."

The first man is one who improves on his opportunities; who is teachable; who gathers unto himself wisdom (knowledge), and by use of wisdom gathers riches and comfort; "to him shall be given." That means profit.

The second man is one who refuses to absorb knowledge; refuses to believe in his own progress; refuses to make of himself, his dairy and his farm, a part of the dairy progress, that is going on all around him. "From him shall be taken (in the necessary cost of handling his milk) even that which he hath. That means loss.

Who is to blame? Is it the creamery or cheese factory? No. It is the man who thinks he cannot afford to know more and do better.

The Farm Separator.

ED. HOARD'S DAIRYMAN:—Thinking that my experience with a hand separator might be of some use to R. M. G. I take pleasure in giving it.

We tried selling milk, and found it unprofitable. The milk brought back was unfit to feed anything. We found we could make more money by selling butter than cream. The item of buttermilk was an object.

We have a rather poor butter market here, usually. We generally sell the butter fresh from the churn. Taking these things into consideration, together with the fact that we had no ice, and pumped water by hand, would have a tendency to make the results from a separator show up better than if we had had better conveniences for handling milk.

The use of the separator since May, shows that they will pay for themselves in a number of ways, inside of a year's time. They will increase the yield of cream or butter from 15 to 25%, and in some cases even more.

The advantage of having the milk warm and sweet, without cooling, and then heating, is worth something to the calves.

If the milk and cream are handled properly, a separator insures clean butter. I think it much easier to clean a separator, if not too complicated, then to wash the necessary cans connected with handling milk any other way.

A separator should be cleaned after each run, to insure perfect work and a clean product. A few people imagine that they clean a separator by running hot water through it. My experience has been somewhat limited, regarding different machines, although I have discovered that the best way to find out which machine skims the cleanest, is to skim carefully, an equal number of pounds of milk in each machine, ripen the cream and churn. The scales will tell the story.

Some of the newer and cheaper machines do the work as well, and will last as long as the old and high priced ones. Easy running qualities, together with extreme simplicity, should guide a man to considerable extent. That the cream from one separator is possessed of greater churnability, than that from another, is a myth. A machine that will not do satisfactory work, under unfavorable conditions, is to be avoided. E C. H

GLOSSARY.

Collodion, a mixture of gun cotton and ether that dries quickly in a thin transparent film.

Peptone, a soluble nitrogenous product that is readily assimilated by living animals and some vegetable cells.

CONTAGIOUS PLEURO-PNEUMONIA.

The interest in this disease in the United States is not so great as some years ago, because it has been practically exterminated by the vigorous efforts of the National Department of Agriculture. Pleuro-pneumonia is widely spread over the European continent, and was introduced into this country from Europe about the middle of the present century. Strenuous endeavors were made at various times by several of the eastern states to prevent its spread, but so long as no concerted action was taken, all their efforts in checking its progress were unsuccessful. The attitude of some of the European governments in excluding cattle from American sources because of the existence of the disease in the United States, brought the subject into such prominence that the government authorities were impelled to inaugurate severe measures to wipe out the disease, and thus protect our exports. As a result, this country is now free from the disease, and so long as proper care is observed in the importation of cattle from infected regions, there will probably be no trouble in the future.

One of the difficulties that attended the eradication of the disease was the fact that the germ causing it was unknown, and hence, the life history of the germ, how it acted outside of the body of the animal, and the manner in which the contagion was contracted were not perfectly understood. For years, strenuous endeavors have been made by numerous investigators to find the organism that was the cause of the contagion. The germ theory of disease has now been so thoroughly established in connection with most diseases of this class that the presumption is always in favor of the view that a communicable disease of this character is caused by some kind of a parasite. In a considerable number of maladies the most persistent and exhaustive studies have failed to reveal the causal germ. In some cases it is probably because the methods of investigation have not been directed in the proper channel; in others, because the appliances are insufficient. In the case of pleuro-pneumonia, the failure to find the specific germ was due to the latter fact, for within the past year it has been discovered. This important advance in our knowledge of animal diseases was made by Nocard, the director of the French National Veterinary College, at Alfort.

He had noted the fact that the disease germ evidently existed in the clear yellow exudate that was found in the lungs of an affected animal, but no amount of research rewarded his efforts to detect the specific microbe. At last he hit upon a method that proved successful. Taking small capsules of collodion filled with beef broth, he inoculated some with the virulent liquid from the lungs. These were then sealed, and introduced into the body cavity of rabbits and cows. While these porous sacks permitted the passage of the body fluids in and out, they obstructed the passage of either the animal cells or the supposed organism of the disease. The removal of these capsules after a while, showed that the fluids had become more albuminous and cloudy. A microscopical examination revealed in them highly refractive motile bodies, so small that their form could not be determined, even after they were stained.

These structures he later proved to be the causal organism, which had been able to grow in the animal body, although isolated from the cells of the blood by the collodion membrane. Uninoculated sacks filled with beef broth, and inoculated sacks heated to a degree sufficient to kill the germ failed to show any of these refractive granules when incubated in body of animal. This germ possesses the unique distinction of being the smallest one yet discovered. Indeed, the perfection of our microscopical instruments

DON'T BE AFRAID about this Dairy Business being overdone. There are less cows in proportion to the number of inhabitants in these United States than ever before. There are two things it is safe to borrow money for to purchase, A GOOD COW and A YEAR'S SUBSCRIPTION TO HOARD'S DAIRYMAN. Thousands of witnesses will so testify. And think of it, "O, ye of little faith!" less than 2 cents a week, or the price of a postage stamp. The price of a cheap cigar will send you the DAIRYMAN for two weeks and a half. It will give you new ideas; new and better methods. It will show you where you are losing money, yea, many times the cost of the paper. Subscribe for it. Read it. Digest it. Follow its suggestions as far as you can. It stands in the front of all other journals in the land on this question. You cannot afford to be without it. Think of it.

at the presen time does not permit an accurate determination of its form and size. It possesses another peculiarity—the difficulty with which it can be cultivated on artificial media. Nocard has finally succeeded in finding a substance on which it will grow (peptone and blood serum from rabbits.)

This long and arduous piece of scientific research has at last given us the connecting link between the causal organism and the disease as it exists in cattle. It is quite probable that this step will prove to be of more than merely scientific interest, as it will afford a solid and substantial basis for future investigation. The next advance will doubtless be the immunization of animals with the products of the disease germ. When this is accomplished, the disease can be more easily prevented. This course is more than probable, as it is already recognized that under natural conditions, animals sometimes acquire an immunity from the original attack.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc, and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form, or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained, by some, that the fat in the milk comes, largely, from the crude fat in the food, but it has been demonstrated that it is not absolutely necessary for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS *Protein*	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

WHAT TO GROW FOR MILCH COWS IN KENTUCKY?

What is best to sow or plant with which to feed 8 head of Jersey cows next winter? I am located in about the center of the blue grass region of Kentucky. P. H. T.

Donerail, Ky.

First of all, corn, especially for silage. It makes no difference whether one is in Kentucky, Georgia or Wisconsin, there is nothing that can be produced from the soil better adapted for feeding to milch cows, as a part of their daily allowance in winter, and to supplement the short pastures of summer, than corn silage. In Wisconsin we advocate growing clover to feed with silage. In Kentucky we can also advocate clover, and in connection with that, cow peas to be cured as hay.

CREAM FOR MARKET.

I keep eight cows and take pretty good care of them. Have been making butter, but in the summer it gets pretty low in price, sometimes. I put it up in one pound prints.

I have ordered a U. S. separator and would like to sell cream in the summer, if I can. Now, in selling cream for ice-cream is it valued by the amount of butter fat in the cream, or not?

What per cent of fat should good cream contain, and price? How should I handle it. I live five miles from town and would have to haul it in wagon. W. S.

Fayette Co., Pa.

The price you can get for your cream will depend largely upon your market. It may bring anywhere from 20 to 40 cents, per quart retail, for 20% cream. Perhaps as good a plan as any is that proposed by the Wisconsin Experiment Station, of charging 1 cent for each per cent of fat present in the cream. This would do for the average city trade, but you may have to modify it to suit your conditions.

Separate your cream, cool well, and for family trade, put up in pint and half pint bottles. Keep it on ice until ready to deliver. Keep bottles and surroundings perfectly clean and sweet, and remember that cream will take up a taint with great readiness. Twenty per cent fat is a good average to begin on, but you may find that part of your trade will want a richer article.

A MICHIGAN RATION.

I have timothy hay at $9 per ton, corn meal at $15 per ton, wheat bran at $17, oil meal from Chicago at $1.35 per cwt. I can get gluten feed at $17.50, but have not used any. Would like to know which is the cheaper feed to use, corn meal at $15, or gluten feed at $17.50, or should both be fed?

My cows give from 8 pounds to 16 pounds of milk at each milking. They are mostly grade Jerseys, and I want to feed for cream.

Grandville, Mich. F. B. R.

The relative value of feeds depends largely, if not altogether, upon the uses to be made of them, and the results desired. For the purpose of simply maintaining the animal economy, that is, to supply the food of support, corn meal is much more valuable than bran or gluten feed, or almost any other grain that can be mentioned. Corn meal is also one of the best feeds to supplement alfalfa hay. On the other hand, if one has timothy hay for roughage, he can hardly afford to use corn meal, even though it were offered him as a gift. Timothy hay furnishes an excess of those elements which predominate in corn meal. It is low in protein and high in carbohydrates and fat. Therefore, one can much better afford to pay $3 or $4 a ton more for bran or gluten feed than for corn meal. As will be seen in the following formula, gluten feed is much richer in protein than bran, and hence if no regard was to be given to other considerations, it could be used to the entire exclusion of bran, but experience seems to have established the conclusion that it is not prudent to rely exclusively upon any one kind of feed, and that there is a limit with many feeds beyond which it is not safe to go. With cotton seed meal this limit is two to three pounds, with gluten meal it is three to four pounds, with gluten feed perhaps it would be five to six pounds, with malt sprouts four to six pounds. There are various reasons for these limitations; some have regard to quality of resulting product, some to the health of the cow and others to the maintenance of her appetite.

A cow will relish certain feeds, if given in limited quantities, but soon tires of them if the quantity is much increased. This is particularly true of malt sprouts, and measurably so of gluten feed. The secret of money making with the dairy cow is to stimulate her appetite in all legitimate ways, getting her to consume the largest amount of feed consistent with health. The dairyman's profit comes exclusively from the amount of feed his cow eats over and above that required for her daily maintenance. It stands to reason that cows giving 16 pounds milk a day, require less feed than those giving 32 pounds per day. It is, therefore, impracticable to submit a single formula, with the idea that it will be equally well adapted to all the cows in the herd. What we aim to do, is to suggest what will probably prove a fair average, giving some cows more, and some cows less, according to the varying ability to make profitable use of it. To the cow that gives 30 pounds of milk a day, increase the allowance of grain, to the cow that gives only 16 pounds a day, reduce the allowance of grain. Used in this way the following formula ought to produce satisfactory returns:

FORMULA FOR RATION.	*Dry Matter.*	*Digestible Nutrients* Protein.	Carbohydrates	Ether Extract
18 lbs. timothy hay...	15.62	.50	7.90	25
5 lbs. gluten feed.....	4.61	1.02	2.42	.25
5 lbs. bran.....	4.41	.63	1.93	.15
Totals.....	24.64	2.15	12.25	.65

BEVELING STAVES FOR SILO, ETC.

1. Would like to know why you recommend not to bevel or dowel a stave silo.

2. How should the staves be placed in the foundation?

3. If the inside is tarred or whitewashed, should the outside be painted? R.

Mich.

1. The only reason we can give for the advice above referred to, lies in the fact that scores of our readers have reported to us that they have found beveling and doweling of staves entirely unnecessary. We have had no personal experience with stave silos, but we can readily see that the bringing together of the two inner corners of adjoining staves, with sufficient tension on the hoops, would result in making a joint absolutely air and water proof, and that is all that is required in the construction of silos. It is of course quite possible to accomplish this when the staves are beveled, and we can readily understand how dowel pins would help to keep the staves in place. There is, therefore, no particular objection to beveling the edges or inserting dowel pins, but if credit is to be given to the testimony which reaches us, these things are not absolutely necessary.

2. So many inquiries are coming to us, as well from old subscribers as from new, we have deemed it expedient to republish directions for building stave silos, and the same will be found in another part of this issue.

3. The question of painting silos is largely a matter of taste with each individual. Of course ordinary paint should not be put in the inside, and we have some doubt as to whether it would be expedient to use coal tar or any other surfacing on the inside of the stave silo. In any event the lumber should be thoroughly seasoned, through and through, before paint of any kind is applied to its surface.

TESTING MILK AND CREAM —INSURANCE.—KEEPING MILK OVER SUNDAY.

Will you please answer these questions:

1st. How to give a fair test where some of the milk is separated at home and some at the factory.

2nd. Where can we get a reliable insurance on the building and machinery at a reasonable rate? We are now giving 3% for one year.

3rd. How to manage the milk if we do not run Sundays in hot weather.

Brown Co., Kan. N. P. E.

1st. If you have the necessary apparatus you can test both the cream and milk, and credit the patron with exactly the amount of fat furnished. It must be remembered, however, that cream, from its greater per cent of fat, requires more care in testing, or costly mistakes are liable to be made. The proper apparatus and method must be used, and these being provided, there will be no difficulty in the testing and division of the proceeds.

2nd. Apply to the Dairy Mutual Insurance Co., Lisbon, Iowa.

3d. If you have plenty of cold water (below 50°) and a double tank arranged so as to allow the water to flow constantly around the milk, you can keep it without difficulty. The milk must be well stirred till the whole body is down to 50° before it is allowed to stand. Keep it well covered, so that the surface of the milk will not get warm from being exposed to the air, or that part will sour. If you have not a good supply of cold water, it would be best to make provision for pasteurizing the cream, at least. The pasteurzing of a large body of milk without special apparatus, is slow and expensive, and should not be undertaken without the proper apparatus.

A CONNECTICUT RATION.

Is a properly balanced ration consisting of mixed hay, bran, fine middlings and cotton seed meal all right and economical, or would better results be obtained by using some hominy chop or corn meal? Cows are part fresh and part milked 5 to 6 months.

Chop and middlings cost 95 cents per 100 pounds, bran 85 cents, cotton seed meal $1.15, old process linseed meal $1.40. J. E. P.

Moosup, Conn.

There seems to be an impression that middlings are a far better feed for milch cows than bran, and there are any number of dairymen who are convinced that such is the fact. When one talks with them, they pretend to fall back upon their experience, but cross examination proves that they have never weighed the feed given their cows, and therefore, never made intelligent conclusions as to the relative value of these feeds, pound for pound. They are accustomed to go to the bin of feed, take the measure, and because bran is light and bulky they think a measurefull of it a large allowance. If the bin contains middlings, they fill the measure half full, and looking at it conclude that it is "stingy" to put so little feed before a good cow, and then they dip a second time. The result is that when feeding middlings, they actually feed from 50 to 100 per cent more in weight than when feeding bran, and under such circumstances it is not at all surprising that they get better results.

The best answer we can make to the above inquiry, is to submit the following formula, which shows the selections we would make, having regard to the analyses and prices of the feeds named:

FORMULA FOR RATION.	*Dry Matter.*	*Digestible Nutrients* Protein.	Carbohydrates	Ether Extract
20 lbs. mixed hay....	17.16	.96	7.92	.32
6 lbs. bran.....	5.29	.75	2.32	.18
1 lb. cotton seed meal	.92	.37	.17	.09
1 lb. linseed meal...	.91	.29	.33	.07
Total.....	24.28	2.37	10.74	.66

A MICHIGAN RATION.

Clover hay is out of the question here, timothy being the only kind to be had for love or money; am out of corn stover; have some corn ensilage left; am milking eleven grade Jerseys. What can I feed to keep up

flow of milk? Bran $16, oil meal $24, corn meal $16; have plenty of rye and wheat straw, but don't count on that, though it is bright and nice. Do not know what gluten meal and gluten feed can be bought for. Can I make up a good ration of the above named articles? And at what price can I afford to buy the last named feeds?

Hudsonville, Mich. W. W.

We give below two formulas, either one of which makes a fairly good minimum ration for cows not too far advanced in lactation. A comparison of them will indicate which feeds will be most profitable to purchase:

NO. 1.

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. silage	5.28	.26	2.80	.14
10 lbs. timothy hay	8.68	.28	4.34	.14
2 lbs. oil meal	1.82	.59	.65	.14
2 lbs. corn meal	1.78	.16	1.33	.09
8 lbs. bran	7.05	1.09	3.09	.24
Totals	24 6	2.29	12.21	.75

NO. 2.

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. silage	3.28	.26	2.80	.14
10 lbs. timothy hay	8.68	.28	4.34	.14
2 lbs. oil meal	1.82	.59	.65	.14
2 lbs. corn meal	1 78	16	1.33	.09
3 lbs. bran	2.64	.38	1.16	.24
3 lbs. gluten feed	2.77	.61	2.45	.15
Totals	22.87	2.28	11.73	.75

In the above, 3 lbs. gluten feed takes the place of 5 lbs. bran.

CANADA PEAS COMPARED WITH COW PEAS.

Do you think the Canada pea is just as valuable, if cured, for milk cows, as the so-called cow peas? To what soil are they best adapted? Could they be raised successfully on marsh land? Could one expect to get a good crop, if cow peas are sown about June 15th to the first of July, in this region??

Watertown, Wis. M. R.

We would not venture to sow any considerable acreage of cow peas in Wisconsin, at present. As we have said before, doubtless some early maturing variety will be produced which can be successfully grown in this latitude, but at present it would be extra hazardous to put one's main reliance upon them.

Cow pea hay carries 9.3% digestible protein, while that of Canada peas has only 7.6%. The former is, therefore, the more valuable for milch cows. A mixture of Canada peas and oats has proved a very successful and profitable crop in Wisconsin. Sow the peas as early as the land can be worked. Plow them under 4 inches deep and then in a week or ten days sow oats over the land broadcast, and harrow them in. Use from 1½ to 2 bushels of peas per acre for seed, and the same quantity of oats. Harvest and cure for hay before the peas are ripe enough to shell.

We think it very doubtful whether the Canada pea would do well on marsh land, partly because of the difficulty of getting in the seed early enough, and partly because this ground is not drouth resisting. The cow pea would probably do better on such ground than the Canada pea. We should be glad to have this inquirer try both, and report the results.

BALANCED SILAGE.

A Connecticut reader writes as follows: "A prominent seedsman advertises the soy bean in connection with silage as making a complete ration without grain. Is it practicable?"

We think the combination of soy beans with corn would make excellent silage, but not by any means a complete ration. Soy bean silage contains 2.7% digestible protein; corn silage 1.3% digestible protein. If these were combined in equal quantities the mixture would contain 2% digestible protein. In order therefore, to secure the needed amount of protein for each day, it would be necessary for the cow to eat over 100 pounds of the silage; but this of course is quite impracticable, if not impossible. This combination silage would, however, very materially, lessen the demand for the high priced by-products, and is in line with the suggestion made some years ago by Prof. Robertson, of Canada, for growing corn, horse beans and sun flowers for silage.

CLEVELAND LINSEED MEAL FOR CALVES.

Is the steam cooked linseed meal, advertised in your columns by the Cleveland Linseed Oil Co., good for feeding to calves? Is it as good as old process oil meal, and how does it differ from it? J. F. B.

Spring Hill, Penn.

We have never used this Cleveland meal for calves, but should judge from its appearance that it would prove quite satisfactory. It differs from old process meal by having a little more protein and not quite so much fat. Some time ago we discarded the use of oil meal entirely for calves, using, when anything was used, simply ground flax seed. Quite a goodly number of successful dairymen use neither, but substitute whole oats, commencing with small allowances when the calves get to be three or four weeks old, and gradually increasing as the calf gets older.

COWS COUGH.

Several of my cows have a slight cough, especially noticeable when feeding. Feed is timothy hay, and two parts bran, two parts meal and one part cotton seed meal. Cows have good appetites and are sleek and in good dairy condition.

The DAIRYMAN is a welcome visitor and one which I do not care to get along without.

Huntington, Conn. D. H.

We do not think you need to worry about the cows, at least for the present. The probability is that when they get out to pasture they will be all right. If not, it might be wise to call in some expert.

SILO BOTTOM.

I understand that the concrete bottom should be joined to the staves in such a manner that there will be no chance for the air to get to the silage. How is this best accomplished? W. L.

Utica, Pa.

Make a little trench and set the staves in it; fill inside and out with cement. Dish the dirt inside so that the center is a little lower than the sides and then floor with cement or well tramped clay. On another page, you will find a more elaborate foundation described.

FIRM BUTTER IN WARM WEATHER.

Can you tell me how to keep butter firm in warm weather? T. J. F.

Temperature, of course, is the most important factor, but this can be assisted by feeding.

Cotton seed meal has a very decided effect on the melting point of butter. Fed in reasonable amount, cotton seed and its by-products produce a butter which is firmer and will stand up better in warm weather. When ice is scarce, feeding two to three pounds per cow, per day, will materially assist the butter to "stand up." If you have any means for keeping your butter at 50° F. or below, you can dispense with the cotton seed meal, but as ice is not always to be obtained and as cotton seed meal is a comparatively cheap source of protein, it may be fed to the advantage of both the cow and the butter.

A SILO FOR FIFTEEN COWS.

I keep from 12 to 15 cows. Will it pay me to put up a silo and fill with a tread power? Will a two-horse tread (Chief) be power enough to fill a 60 ton silo? W. H. G.

Medford, Minn.

Fifteen cows will need about 54 tons of ensilage to carry them through. If the experience of others is any proof, it will certainly pay you to put in a silo.

A good two-horse tread will cut and put in silo from 12 to 20 tons per day. A few days' work in filling a silo is a saving to yourself, your cows and your fodder.

AMOUNT OF ACID FOR TESTING MILK.

A certain buttermaker claims that milk testing 6% requires about ⅓ more acid than the test calls for and poor milk correspondingly less. Can you tell us what effect such usage of acid would have on the measurement of the test. W. H. R.

Luana, Ia.

You should not make any change in the amount or quality of the acid used for the test. It was found by long continued experiment, the exact amount to be used and success in testing depends on following the directions exactly. Use the same amount of acid for all milks.

SALTING BUTTER IN THE CHURN.—USE OF PARCHMENT WRAPPING PAPER.

Several writers advocate salting butter in the churn and not working it. How would they manage it and peddle week's out-put once a week in pound prints? Would not the papers be soaked with moisture? I want the simplest and easiest way, but so far all who advocate it speak of putting the butter in jars. Even when I work as much as I dare without spoiling the grain, my papers get soaked and when dried are salty, and I salt only one ounce to a pound. What kind of paper do creameries use, and what do they do to the butter to keep the papers so dry? D. SKELTON.

Connecticut.

The matter of putting butter in jars or molding it into bricks or prints will not affect the manner of working and salting; the only difference is that in the one case the butter is removed from the churn to a jar and in the other from the churn to the table where it is made into rolls, or prints, or such shapes as may be desired. Creameries use parchment paper for wrapping their prints, and if wrappers become more or less brine soaked no harm results. If one was particularly anxious they could omit wrapping the prints until the time for distribution came and then put the wrappers on fresh.

COWS TOO FAT.

Would you please give balanced ration for 25 head of cows, few fresh, others milking from 3 to 7 months, weighing from 800 to 1,000 pounds. Cows are entirely too fleshy; have been feeding about 30 lbs. of well eared ensilage with 3 lbs. cob meal, 4 lbs. bran, 4 lbs. middlings, with clover hay at noon. Ensilage will not last longer than 15th of this month. Have bran at $16 per ton; middlings at $16; cob meal of our grinding. Would you advise gluten feed or cotton seed meal? Have clover hay, also timothy, and cut corn stalks. Want a good ration that will put more in the pail and less on their backs. M. S. S.

We can hardly account for the excess of flesh reported from the ration as fed. There seems to have been the proper allowance of protein and very little, if any, surplus of carbohydrates and fat. Unless there is some mistake in some way in estimating the feed or otherwise, one can hardly escape the conviction that possibly the fault is more with the cows than the feeding. The only thing to do, however, under the circumstances is to try what a change in feed will bring about, reducing the carbohydrates and fat very materially, and leaving the protein where it is, or increasing it. This is the general rule to be followed in all cases. When a dairy cow is increasing too much in flesh, the indications are that she is receiving too much of the flesh forming material, and possibly too little of the milk forming material. Individual cows differ in these respects and the intelligent feeder adapts himself to their pe-

"Winter Finds Out What Summer Lays By."

Be it spring, summer, autumn or winter, someone in the family is "under the weather" from trouble originating in impure blood or irritated condition of the system.

All these, of whatever name, can be cured by the great blood purifier, Hood's Sarsaparilla. *It never disappoints.*

Abscesses—"I am past 54 and my good health is due to Hood's Sarsaparilla and Hood's Pills, which purified my blood and healed the ugly abscesses that troubled me." MRS. BRITTON C. ESTELL, Southard, N. J.

Dyspepsia—"My husband doctored a long time for dyspepsia with only temporary relief. The first bottle of Hood's Sarsaparilla helped and the second cured him. It cured my sick headaches." MRS. MARY A. CLARK, Wilmington, Vt.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Would You Double your trade Mr. Milkman? You can do it by using a CHAMPION MILK COOLER-AERATOR, it don't cost much and its use will make lots of difference in your profits. Our book "MILK" is yours for the asking.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

culiarities. When the first-class dairy cow is giving a large flow of milk and running down in flesh let her have some corn meal in addition to the bran and gluten feed, or cotton seed meal, or other highly nitrogenous feeds. In line with the suggestions above submitted we append the following:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
10 lbs. clover hay	8.47	.68	3.58	.17
5 lbs. timothy.....	4.34	.14	2.17	.07
5 lbs. corn stover.....	2.98	.09	1.62	.04
5 lbs. bran.....	4.41	.63	1.93	15
2 lbs. cotton seed meal	.94	.74	.34	.18
Totals.....	22.14	2 28	9.64	.61

DISCIPLINE OF NEGLIGENT PATRONS.

If a patron in a gathered cream factory sent cream testing only 8% to 12% fat, also 212 spaces, or 22.2 gallons, only churned out 22½ pounds butter, what would you do, take it, or keep him out, as he has been notified twice? Also one patron is slovenly and sends manure in his cream, and no dairy commissioner to see to it. I don't care for such patrons, and the owner of the factory is away and I cannot see him for some time yet. F. W. C.

Maine.

An employe should be extremely cautious about assuming responsibilities not specifically delegated to him by his employer. In this case, it would seem to be the proper thing to write to the owner of the factory and get his instructions in the premises, especially in regard to the patron who delivers low testing cream. The other case, if flagrant and repeated, scarcely permits of delay. No butter maker is justified in receiving filthy cream from any patron. The best manner of procedure is, first to call the patron's attention to the condition of his cream. Show him wherein it is at fault —explain to him that such cream is not only bad in and of itself, but when mixed with other cream injures the whole lot. If he still persists in neglecting his cream, and you do not feel like rejecting it in total, receive it—keep it by itself and make it up into butter by itself, but under no circumstances mix it with the other cream.

PACKING BUTTER TO KEEP.

I wish to pack about 600 pounds butter at the rate of about 50 pounds per week for use in boarding house during August, September and October. Will some one with experience tell me how to do it? I have a separator and grade Jersey cows and have been churning and salting butter very much like W. C. Rockwood describes in March 24th issue of DAIRYMAN. Have been told that butter packed in May will keep better than that packed in June or July.

Morrow Co., Ohio. E. L. B.

It may well be questioned whether it would not pay better to sell the butter made in May and June and "pack" the money received and use it for purchasing fresh made butter in August, September and October. Times change and we change with them. Butter which would have been accounted extra a few years ago, would hardly pass above seconds now. Rapid transit has brought the consumer so much nearer the producer that he demands that not only butter, but everything else, should be brought to him fresh.

However, if our friend concludes to try the experiment in packing butter, to keep for several months, we advise him to get the old-fashioned firkin, have it thoroughly well soaked, rub the sides well with salt, put his butter down. When full, replace the head, having previously put a three-fourths inch hole through same, and then keep the surface of the butter well flooded with strong brine. Store in the coldest room possible; a freezing temperature is best, therefore get as near to it as possible.

The only reason why May butter will keep better than that made in June or July is that weather conditions of the former month are usually more favorable for the production of the higher class article. We used to think that it was wholly a question of temperature, and indeed, in a way it is, but later investigations show that the warmer months are more favorable to the multiplication of bacteria and hence greater care must be exercised to keep them in proper subjection.

Having given our own views as above, we shall be very glad if others will recount their experiences for the benefit of the inquirer.

IS BULL PERMANENTLY INJURED?

Have I spoiled my young Jersey bull? I used him a number of times on heifers when less than a year old and he has not gotten them with calf. He is strong and good size, and am feeding four quarts a day of bran and oil meal with timothy hay. I know I ought to have known better but wanted the heifers to be served and there is no small bull of any merit around here. Will he come right again? D.

Conn.

We do not think the animal is injured—at least not permanently. We suspect he is being feed too high, and suggest that oats be substituted for the bran and oil meal, the amount to be determined by his condition. Do not feed so much as to fatten.

SEPARATOR WORKS IRREGULARLY.

Why does my separator give me cream of different degrees of thickness when conditions are exactly alike? Sometimes it will be thick in the morning, and then again it will be night when it is thick, and perhaps run several days uniformly. — —

Connecticut.

This seems to be a case demanding the personal attention of an expert, and we apprehend such an one would discover that the conditions are not exactly alike. We can do no more than guess that in some way, during the washing or handling of the separator, the adjustment of the cream screw gets changed, and a slight change of this screw will produce very marked changes in the cream.

FEED FOR SHOTES.

Prescribe best ration for shotes weighing 150 to 175 pounds alive, in order to fit for killing the middle of May. Been fed skim milk and middlings during the winter, but at present have no milk. Now being fed 2 pounds middlings, 2 pounds hominy chop and 1 quart corn, each, per day.

Conn. J. E. P.

The amount to be fed to swine during the fattening period must be determined, from day to day, by the intelligence of the person in charge. They should have all they will eat, and not leave any to be wasted. There is so much difference between different animals in regard to the amount, that it is utterly impracticable to attempt an estimate. We cannot say that the mixture now used is not well adapted for the purpose, but we do not find in any of the books on swine feeding, the record of any experiment where hominy chop formed a part of the feed. From the analysis we should be inclined to question whether they are the most appropriate food for this period in feeding, but in the absence of practical experience it would be very foolish in us to condemn them altogether. The corn, if at all dry and hard, should be either thoroughly soaked and softened, or else ground into meal. If ground, it should be thoroughly wet in connection with the middlings, thus making a good substantial slop.

A DIMINUTIVE YIELD OF MILK.

What can be done to a fresh cow to bring her to the full flow of milk? The cow was milked up to the time of calving, once a day, for the last two weeks. She seems perfectly healthy, eats and drinks heartily, but gives only about a pint of milk per milking, twice a day. Have given her one teaspoonful of ginger, one teaspoonful bi-carbonate of soda, and ½ teaspoonful of common salt, twice a day. What would you advise?

Watertown, Wis. SUBSCRIBER.

Our judgment is, that there is no form of medication that can reach difficulties of this character. It is possible, that if you persist in milking, there will be an increased yield, but the chances are, that the cow will never regain her full capacity. This drying off of cows, or milking them at long intervals during the two or three weeks preceding freshening, seems to bring about some decided change in the mammary glands that only time can overcome. We have one cow in our herd, and have other cases reported to us, where persistent milkers have been forced dry with the result of doing them permanent injury. The one thing to be done, in this case, is to wait for results, and be guided accordingly, either in keeping this cow or fattening her for beef.

WHERE TO GET RED POLLS.

Would like to know the address of some breeders of registered Red Poll cattle.

Alsen, S. Dakota. A. S. A.

W. H. Forbes, Clifton, Ohio, in current issues of the DAIRYMAN advertises Red Polls for sale. S.A. Converse, Cresco, Iowa, J. W. Martin, Richland City, Wisconsin, and V. T. Hills, Delaware, Ohio, are among those who have previously advertised these cattle in our columns.

SILAGE FROM CORN AFTER REMOVING EARS.

Which would you consider better, to plant yellow dent corn and put it in a silo with corn on, or plant sweet corn and pick it for a factory, and then put poor corn with stalks in silo? We will take $30 as the average amount received for sweet corn per acre, and to make up this deficit in feed have got to haul grain 12 miles and pay the following prices: Bran $20 per ton, cotton seed meal $24 per ton, oil meal $27 per ton, gluten $27 per ton.

Corn factory 3 miles from farm, and have to take a $35 share or can't plant sweet corn. J. T.

E. Corinth, Me.

Experience has been abundant showing that silage made from corn, after the ears have been removed, is nearly as valuable as when ears are left upon the stalks. This seems hardly possible, but the chemists tell us that fully one-half of the feeding value of the corn crop is in the stalks and leaves. It is not meant that the residue, after removing the ears is worth as much as the entire crop, but that the feeding value per ton is not materially diminished. It would seem, therefore, if one could be reasonably sure of getting $30 per acre for the ears, that this would be more than he could expect from them, or the half of any other corn crop when made into silage.

And in any event he would need some of those protein feeds, and at the prices quoted cotton seed meal is much the cheapest. But with so long a haul, and prices so high, it would seem that our friend ought to set about growing protein feeds like clover and peas.

The matter of taking stock in a canning factory for the purpose of securing a market for the sweet corn, is a business proposition that we cannot advise about.

Have You Been Sick?

Perhaps you have had the grippe or a hard cold. You may be recovering from malaria or a slow fever; or possibly some of the children are just getting over the measles or whooping cough.

Are you recovering as fast as you should? Has not your old trouble left your blood full of impurities? And isn't this the reason you keep so poorly? Don't delay recovery longer but

Take Ayer's Sarsaparilla

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

Holstein Tests.—A Correction.

ED. HOARD'S DAIRYMAN:—Mr. VanValzah asks for an explanation of the mistakes that appear in list of official tests of Holstein-Friesian cows recently published by you.

The mistakes were made in copying. I failed to review the work. They are as follows: Sadie Vale Concordia should have been credited with 20.965 lbs. butter instead of 18.405 lbs; Zady Bergsma with 16.223 lbs. instead of 12.210 lbs. The age of Mutual Friend 2nd's Pauline should have been 2 years, 13 days, instead of 3 years, 17 days.

Yorkville, N Y. S. HOXIE.

Some Nuisances in the City Milk Supply.

ED. HOARD'S DAIRYMAN:—What I here shall mention are things which I personally have had ample opportunity to notice over and over again, and many of which are constantly noticed by numbers of people who are themselves interested in getting good milk for their family use. That those who furnish the large cities with milk and cream, or at least a large majority of them, do not care to exert themselves to produce an extra article either as to purity or richness, is not surprising at all as long as they receive so very slight an encouragement for such efforts.

The fact is, that a very poor and impure article of milk at somewhat lower price in most cases gives both producer and dealer a larger profit than an extraordinary pure and rich article at the higher price

Now there are in every city, two parties who have it altogether in their power to compel the retailer of milk to furnish only a pure and fairly rich article, the Health Department and the consumers.

That the latter class is so indifferent, at least generally, is, to a great extent, simply the cause of ignorance as to the danger which is at all times lurking in impure milk. Nothing less than an epidemic of some contagious disease, proven to have spread through the disease germs in some dairyman's milk, will arouse the average consumer from his carelessness on this important subject.

Yet surely prevention is a great deal better and cheaper than cure. I hold that nothing can be done to arouse public indignation against the many outrageous nuisances committed by so many milk producers and even more so by the retailers and drivers, except just so far as the people are stirred up and educated by their respective health officers and family physicians. Therefore, the only steps which can cause any cure will be improved dairy laws and regulations for delivery of milk in the cities, and their strict enforcement.

It has been a great wonder to all that thus far almost all regulations of the health departments of the various cities of the Union are entirely and only directed against adulterations of some kind, the principal points being that all milk sold must contain a certain percentage of solids and of fat, the latter being generally put altogether too low.

Common sense tells us, that while we do not wish to pay full price for a partly skimmed or adulterated article, still a child or feeble person is exposed to a far greater danger from milk which, while ever so rich, may contain dangerous disease germs; either caused from sickness of the cows, or from unclean milking and handling by careless and untidy persons, from the producer to the retail driver.

I shall try to show some of the most common nuisances, and also how they may be avoided and prohibited.

There are two distinct classes of nuisances connected with the dairy business, especially as applied to city milk supply, which have to be treated separately. I shall first mention those connected with the place of production.

Among these the first is:

THE COW STABLE AND COWS.

The fact is, that while here in Washington, as well as in other cities of the Union, we have laws demanding that milk must only be brought into the city for sale from farms where the stables and cows are kept in a clean and sanitary condition, still a large number of farm dairies are so dirty and nasty, that if the consumer but once took the trouble to look and smell inside of such, he would absolutely quit using milk produced there, especially as a drink, or as the principal nourishment for his children.

The cow's limbs and sides, yes, even their udders, will be found covered with old and dried up manure, which during milking will scatter as a fine dust into the milk pail, and never can be removed again, no matter how fine strainer cloths may be used. The customer, though, will find it by and by at the bottom of his milk jar or pitcher, if left long enough to give it a fair chance to settle. But I guess the majority of city users have become so accustomed to this, that they think it really belongs to milk.

THE FLOOR OF THE STABLE.

No matter whether simply of hard dirt or of planks, is so thoroughly soaked through with urine and manure, that any kind of thorough cleaning is made impossible. The strong smell is always there and can never be removed, and during milking the milk daily absorbs its share, especially as it generally is left in the stable until all cows are milked.

THE HAY AND OTHER FEED

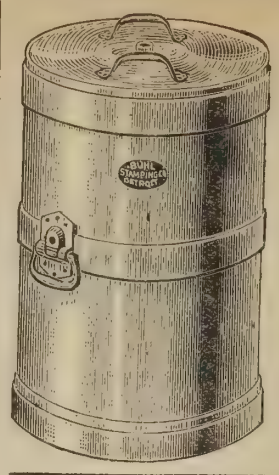
is often kept in the same barn above the cow stable, and has a most excellent chance to absorb its share of these perfumes and must necessarily pass them on into the milk, which then afterwards is called "cowy,"—altogether too nice a name.

The butter makers and cheese makers of our factories also know some of their troubles from these "cowy" perfumes! In winter the stables are often so cold that the cow's feet freeze, and the water is given ice-cold; all of which, of course, causes a decided decrease in the milk yield, as well as in the richness of the milk, and just at the very time when we least can spare it.

In order to get the milk away from the farm, early enough mornings to reach the city breakfast tables, the milking is rushed through too hurridly. The cows are not milked clean; they are handled roughly and harshly by impatient and ill-humored milkers, all of which certainly does not improve matters.

The milk pails and shipping cans have generally been only carelessly cleaned, if it is fair to call it cleaning at all, as at night the milkers wish to get through as quickly as possible. The insides are often washed with only luke warm or cold water, and afterwards rinsed out with cold water, often supplied from some questionable well or cistern.

Hot water or steam is out of the question, and the outside of the cans—well, the part you see may look salable, but please look under the bottom once! Oh, my! It is absolutely an exception that they are washed, (mark it, I speak from what I have observed at railroad depots), and when you keep in mind that these old manure collections are constantly carried into the different city dairies, you can understand where the splendid variety of bacteria came from, which is found in most city milk.



If the milk is cooled at all, it is simply by setting the shipping cans in cold water (often not cold at all) what little time is to spare before it is put in the wagon; the water often only reaches half way up on the can, and if stirred at all it is done very indifferently and insufficiently. Result—the milk retains as much as possible of the "cowy" flavor, and sours very rapidly.

The milkers themselves are as dirty as the cows, of course. How can you expect any man or woman to put on clean clothes to sit down in a manure pile under a filthy cow? No, indeed! On the contrary, they have some old dirty overalls, or overskirts, hanging in the stables, by which they protect themselves, and when these outer garments are washed I don't know. I have never seen them clean in such places as I have spoken of.

If some cow has a bad cough or otherwise shows signs of tuberculosis, or other disease, she is rarely separated from the rest, and often milkers are employed who have consumption and will expectorate on the feed of the cows, and cases have been found where in this way a cow became tuberculous.

HOW MAY WE REMOVE THESE EVILS.

First, by strict dairy laws, and by a more numerous and efficient corps of dairy inspectors. The present force is entirely insufficient, and there is no prospect of having a generally fair milk supply in our cities un-

The Best Factory Cans.

The strong points of the Buhl Factory Cans are their great strength, heavy coating of pure tin, and fine finish. They do not rust like common cans, have no crevices inside, will not leak, and need no repairs. No other cans have the Genuine Heisey Side Hadles.

Look for the Milk Can Trademark.

This Can has 3 welded, tinned, wrought-iron hoops, tinned malleable side handles, and heavy XXXX genuine Cookley K cylinders.

Capacity 15, 20, 30, 40 and 50 gallons.

Refuse imitations. We make all patterns and sizes of Milk Cans, and will gladly mail you our hand-book free.

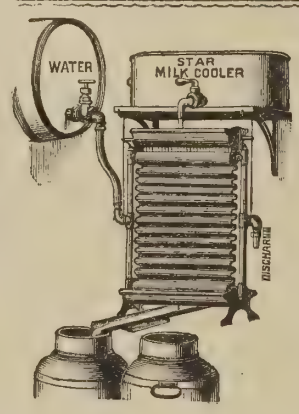
Gluten Feed

is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it.

Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating "Value of Butter Fat in Milk," all FREE if you address

THE GLUCOSE SUGAR REFINING CO.,
DEPARTMENT H. The Rookery, CHICAGO, ILL.



KANSAS CITY, MO., March 15, 1899.

MORRISON MFG. CO., GENTLEMEN:—With regard to your Heel Plate, we would say, it is increasing the sales on your plows very materially. It is easy to appreciate that it is a decided improvement in walking plows. It is the greatest advance made in walking plows for ten years, and that is saying a great deal. Yours truly. BUFORD & GEORGE MFG. CO.

It makes Share last longer, cures winging over, holds the Share sharp twice as long.

A postal will bring a beautiful catalogue.

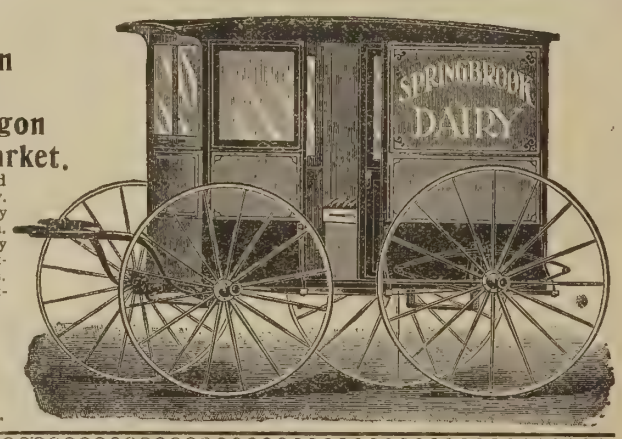
MORRISON MFG. CO., Fort Madison, Iowa.

Star Milk Aerator AND COOLER.

If you have milk worth cooling at all, it is certainly worth while to cool it thoroughly. An efficient Milk Cooler will cool to within two degrees of temperature of water used; the Star does this and also **AERATES.**

If you would like to know the reason why, send for 1899 Catalogue of Sanitary Dairy Apparatus.

To be had for the asking.



STAR MILK COOLER CO., Haddonfield N. J.

BRABAZON'S POULTRY CATALOGUE FREE! It's a beauty; over 50 colored plates. Illustrates and describes fine Turkeys, Geese, Ducks and chickens; gives prices of fowls & eggs. Finest Buyer's Guide published. Inclose 10c. for postage, etc. J. R. Brabazon, Jr. & Co., Box 58, Delavan, Wis.

The YOUNG AERATOR And Cooler

Needs no water or ice, removes all odors and gases, warranted to keep milk sweet from 6 to 12 hours longer than any machine on the market or money refunded. Circulars free,

W. H. YOUNG,
Box 135, Aurora, Ill.

til the system of inspection is carried on more vigorously and more intelligently.

Too often men are employed who know nothing about cows and milk, or the treatment of either, and such inspection is simply ridiculous. But all this means more money to be paid by somebody; and yet, it is a very sure thing, that every dollar spent intelligently for the improvement of our city milk supply, will be a paying investment, as it will save far more from disease and even death, than can be counted in cash.

J. MOLDENHAWER.

[*To be continued.*]

The Influence of the Sire.

ED. HOARD'S DAIRYMAN:—I was very much interested in the paper, "Mistakes in Dairying," read before the Kane Co., Ill., Institute by H. B. Gurler, and published in the DAIRYMAN of April 7th.

I believe the article to be very practical and right to the point. Among the many good suggestions made, he urges the dairymen to raise the heifer calves from their best cows.

I was somewhat surprised that he said nothing in this connection relative to the sire used, for I believe it is just as important to use a sire whose ancestors, for several generations back, on both sides, have proven large producers, both in quantity and quality of milk. With a long experience in breeding and dairying, I am fully convinced that the sire has as much, or even more, influence on the future usefulness of the offspring, than the dam; and I would say to dairymen, use great care in selecting your sire. Choose from the breed you prefer. Be sure that his ancestors are large producers and of the most desirable families.

The bull is half the coming herd. Then, as Mr. Gurler suggests, choose heifer calves from cows that have the qualities you wish to predominate in your herd. Then you will have every reason to expect you can grow up a herd that will excell their dams.

Lacona, N. Y. H. S.

THE RECORD OF BAD JUDGMENT.

Our readers will remember that in November last we published the record of the Meriden creamery, in Kansas, or rather the record of many of its patrons. It was there shown that some of the herds produced as low as only nine dollars per cow for the year.

Here is a ray of light let into the reason of such low, unprofitable work, by one of our Kansas exchanges:

Out of eighty-two patrons of the Meriden Creamery from which we have reports for 1897, there were only nineteen, or twenty-three per cent, that were using pure blood sires; and two of these had Herefords, and one an Aberdeen Angus, animals that as a breed are unfit for profitable production of milk. This leaves seventy-seven per cent that bred to grades or common bulls of no particular breed. Some of those bred to any kind of a bull they could find to get fresh cows. One man bred to a Red Polled because he was working for red color. Another man did not know what kind of a bull he had last year, but said he had a fine one this year. When asked the breed, he replied: "Don't know, guess he is a Red Polled." Right here lies the secret of many of the low yields of our Kansas cows. Our farmers little realize how extravagant they are in using a common or ordinary bull. Their short sighted policy leads them to believe that because a good animal costs $100, it would be money thrown away to invest, when in reality it would be money in their pockets. A dairyman can much better afford to pay $100 for a good bull, than to accept a poor one as a gift.

DAIRY MARKETS.

ELGIN, Ill., April 17—Butter—Steady; offerings 164 tubs, all sold at 19c. Official market 18½c.

CHICAGO, Ill., April 17—Butter—Creamery extra, 18½c; firsts, creameries, 17@17½c; seconds 14@15c; dairies, selections, 17c; No. 1, 13@14c; No. 2, 12@12½c; extra ladles 14c.

Eggs—Fresh, at mark, cases included, sold at 12½c

Cheese—Full cream, Twins good to choice, 11½@12c; new Twins, 11@11¾c; Young America, 12@12¼c; Swiss, 10½@12½c; Limburger, 8½@9½c; Bricks 11@12¼c.

MILWAUKEE, Wis., April 17—Butter—Creamery, fancy prints, per pound, 19c; extras 19c; firsts 17@18c; seconds 15@16c; imitations 15@16c; Dairy, selections, per pound, 14@15c. Roll, fair to choice fresh, per lb, 12@13c. Market weak and tending lower, under liberal accumulations as trade is limited to small lots; receipts 9,755 pounds.

Cheese—American Full Cream—October Twins 11¼@12c; new, per pound 10½@11c. Brick; October supply exhausted; new, per pound 10½@11c; Limburger, fall, choice, per pound 9@ 0c; winter made 8@9c. Swiss, Drum, choice 12½@13c; block choice 10½@11c. Market quiet and easy, with receipts of 2,7c0 pounds. Swiss alone is firm.

Eggs—Fresh, per doz. 11c. Market unchanged, with ample receipts, 517 cases; trade is fairly active.

SHEBOYGAN FALLS, April, 12—336 boxes of cheese were placed on the board. All were sold. 35 boxes Twins at 11¼c, 175 cases Young Americas at 10¼c, 60 cases at 10⅝c, 35 Daises at 11⅞c, and 10 cases Longhorns at 10½c.

SHEBOYGAN, Wis., April 12—The sales reported to-day were 100 boxes Twins at . 11½c, and 150 csaes Young Amercias at 11c.

PLYMOUTH, Wis., April 11—The Plymouth Dairy Board held its first sales of the season to day. Market active with sales of 147 boxes Twins at 11⅝c, and 50 boxes Americas at 10⅞c.

PHILADELPHIA, Pa., April, 17—Butter—Solid packed separator creamery, extra, 19½c; creamery, firsts, 18½@19c; seconds, 17@18c; imitation creamery, extra, 17c, firsts, 15c; seconds, 13c Ladle packed, extra, 16c; firsts, 15c; seconds, 14c. Print butter, creamery, extra, 21c; firsts, 20c; seconds, 18c.

Eggs—Pennsylvania near by 13½c; western, 14c; southwestern, 13½@14c; southern, 13c.

ST. LOUIS, Mo., April 17—Butter—Firm; creamery, 18@22c; dairy, 14@19c.

Eggs—Lower, 11c.

KANSAS CITY, Mo., April 17—Butter—Lower; creamery, 14@17c; dairy, 15c.

Eggs—Steady; fresh, 11½c.

CINCINNATI, O. April 17—Butter dull.

Eggs—Firm; 11c.

Cheese—Firm; good to prime Ohio flat, 11½c

NEW YORK, April 17—Butter—Creamery, western extras, 18½@19c; firsts, 18@18½c; state extras, 19c; firsts, 18@18½c.

Cheese—State full cream, large colored or white fancy. 12@12¼c; choice, 11¼@11¾c; small, fancy, 12¾@13c.

Eggs—State, Pa. and Western, 14@14½c.

BALTIMORE, Md., April 17—Butter—Market firm; creamery, separator, extra, 22@23c; extra firsts, 21@22c; creamery firsts, 20c; ladle, extra 15@16c; western store packed, 11@13c.

Eggs—Market firm; strictly fresh stock, 12½@13c; duck eggs, 12c per dozen.

NEW YORK MARKET.

NEW YORK, April 15.—Butter—Receipts for the week, 35,658 packages. Exports for the week. 495 packages. There was less trade from all quarters the past week, arrivals were quite liberal, prices heavy and market closed with a decline of fully 2c per pound on all grades of fresh butter, except ladles, which held their own. Complaints were quite general from retail buyers that quality of fresh creameries was not up to the standard; a good many of the Western marks showing lack of good feeding, poor body, and when exposed to the air on the counters for retailing, went off in quality very quickly. Extra Creameries are selling at 19c and under grades at prices ranging from 16@18c. New York State Dairy selections wanted at 18c and fair to good quality sells slowly at 15@17c. Ladles are in light supply and sell on arrival at full prices. We quote: Creamery, extra, 19c; medium 18@19c; poor, 15@17c, Dairy, extra, 18c; medium, 16@17c; poor, 14@15c.

Cheese—Receipts for the week, 6,623 boxes. Exports for the week 2,188 boxes Exporters are entirely out of the market and will be until the new make arrives in quantity enough to materially reduce quotations. Old cheese are in small compass and only hand to mouth business doing; sales are reported of fancy small sizes colored cheese at 13c and large at 12@12½c. White cheese selling at 11¼@12½c; new cheese are in light supply with prices weak and very irregular. We note sales in the interior of the state of about 300 boxes small colored at 11½c. We quote: Old cheese, small, extra, 12½@13c: medium 11½@12c; poor, 10@11c. Old cheese, large, extra, 12@12½c; medium, 11@11½c; poor, 9@10c. New cheese, small, extra, 11½@12c; medium, 9@10c; poor, 5@7c. New cheese, large, 10½@11½c; medium, 9@10c; poor, 5@6c.

Eggs Receipts for the week, 63,931 cases. Prices have been well maintained, receipts all taken and market closes firm. We quote: New York and Pennsylvania, per doz, 14@14¼c; Northern and Western, 13¾@14c; Southern, 13@13½c.

D. W. LEWIS & Co.
117 Chambers Street, New York.

BALTIMORE MARKET.

BALTIMORE, April 13—The receipts of separator creamery butter for the past week has been light, and the quality disappointing; the defects in the favorite marks from the gilt edge districts of Illinois, are particularly noticeable and annoying, because so much is expected from them in points of flavor and finish. Latterly, when the salesmen expose these silk stocking lines for sale, as salesmen will talk, begin to sing their praise before smelling the samples on the triers, the expressions on their faces are studies for physiognomists and actors; the something hoped for and expected is not there, and to change the chagrin at not finding it to an affected satisfaction at the displeasing condition, overtaxes the skill of the many, and emphasizes the skillfulness of the few. Where the perfume of new milk has been lost in the manufacture of to day, that was so eagerly awaited during the winters of not very long ago, and was so welcome and grateful when it arrived in the full new milk product? Has the present method of advanced art, robbed us of that charm of spring, when the house wife's fancy lightly turned to butter, new? Gathered cream, imitation creamery and ladle packed goods all are in quite light receipt, and generally meet with prompt sales on arrival, and relatively good prices. The floors are in the same bare condition noticed last week. There is the usual distributive business in blocks and prints of creamery butter, and some little doing in other varieties and lower grades; rolls are scarce; all good to choice is in quick demand.

Creamery separator, extra, 22c; firsts, 20@21c seconds, 18@19c. Gathered cream, extra, 19c; firsts, 18c; seconds, 17c. Ohio, extra, 20@21c; firsts, 19@20c; seconds, 17@18c. Rolls, extra, 15c; firsts, 13@14c; seconds, 12@13c. W. Va. Roll, extra, 13@14c; firsts, 12c; seconds, 11@12c. Creamery Blocks, (2 lbs.) extra, 23@24c: firsts, 21@22c; seconds, 19@20c Creamery Prints, (½ lb.) extra, 23@24c, firsts, 20@21 c; seconds, 18@20. Maryland, Va. and Pa., extra, 20c; firsts, 19c; seconds, 18@20c.

Eggs—Our market rules very firm, under continued light receipts; the trade is showing less hesitancy in taking hold, consequently our receivers, so far, have been able to keep all receipts of hen eggs well cleaned up from day to day. Duck eggs—as we predicted in our issue of last week, it was only a matter of a short time, that they would bring any more than hen eggs; well, that time has arrived, and now hen eggs have the preference, at the same price. The season on duck eggs is virtually over. Hen eggs are not only firm, but active at 12½ cents.

Western Md. and Penn., per doz. 12½c. Eastern Shore, (Md. and Va.) 12½c. Virginia, 12½c. Western and W. Va. 12½c. Southern, 12c. Duck eggs near by 12c. Duck eggs, Western and Southern, 12c. Goose eggs, 18@ 0c.

Cheese—Receipt light; demand good; market firm.

New York State Cheddars, fine, 12@12½c; choice, 11@11½c; fair, 9@10c. Flats, fine, 12@12½c; choice, 11¼@11¾c; fair, 9@9½c. Small, fine, 12¼@12¾c; choice, 12@12½c; fair, 9½@10c. Ohio Flats, fine, 11@11½c; choice, 10½@11c: fair, 8½@9c. Ohio Picnic, fine, 11½@12c; choice, 10@11c; fair, 9½@10c. Swiss Cheese, fine, 11@12c; choice, 10c; fair, 8½@9c.

301 Exchange Place. G. M. LAMB & BRO.

FOREIGN MARKET.

BOSTON, April 15.—Cable advices of this date from the principal markets of Great Britain to George A. Cochrane give butter markets as less active. Seasonable weather and increased receipts of Continental and Irish give buyers an advantage, which they are pressing for all it is worth, and they have established a decline of 2@3s on all grades. While arrivals from Australia, America and Canada are light, there are sufficient stocks to prevent holders from obtaining any advantage. Finest Australian is selling at 2⁰@20½c, with very good value to be had at 19@19½c A little fancy fresh Canadian in boxes is selling in the northern markets at 21@22c. American butters meet with a very indifferent demand. Creameries in tubs are offered from 17@19c, but clearances are not being made as fast as holders would like to see. Imitations are selling at 16@17c Ladles continue a dull sale at 15c downwards.

Cheese markets are fairly steady. Stocks are being gradually reduced, but little or no advance on present prices is looked for as high prices have checked the consumption Finest Septembers and Octobers are held at 11½@11¾c with occasional sales of something extra fancy in the way of Canadians at 12c. Anything from 11c downwards is much wanted and in light supply.

ALL ABOUT
CREAM SEPARATORS

Why the improved and patent protected "Alpha" disc machines are as much superior to the older types of separators first made by the De Laval Company and now by several imitators as are such older pattern machines to gravity setting.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—Fifteen h p. boiler and 15 h. p upright high speed engine nearly new, also 6 h. p engine. GEO. WOODRUFF, Adm'r, Janesville, Wis. 10-3 □

Buttermaker wants position. Can give good reference. Understands running all kinds of machinery. Address P. A P, 2d Flat, 266 Sedgwick St., Chicago, Ill.

For Sale—One No. 2 De Laval Turbine separator. Has been used but four months. It is in first-class order and good as new. Will be sold at a reasonable price. Address LANCASTER CREAMERY CO., Lancaster, Pa.

For Sale—In vicinity of Tampa, Fla., 15 miles by water from street car line, a 255-acre farm, ½ mile bay front, good wharf with beach extending to house Well fenced in and divided by a netting into a field and two pastures 20 to 40 acres clear, rich sandy loam underlaid with clay, fixed for irrigation, crops growing. Nice two-story residence. Launch with 3 h. p. gasoline engine, 2 mules, 21 milch cows, 1 Jersey bull, calves, hogs, poultry, ducks, building material, etc. Farming tools, cream separator, buggy, etc. For further particulars, address P. O. Box 133, Tampa, Fla. 10 sp

For Sale—Six full-blood and three high grade Guernsey cows. Also one two-year-old bull for $500.00 if taken at once. Address L. A. SPRAGUE, Marshall, Minn.

Dairyman Wanted—Married man; must be first-class butter maker and have had experience with Jersey or other dairy cattle. Must be able to furnish good references as to character and ability. Wife must be willing to take some boarders. Address with full particulars, W. G. APPLEBY, Fillmore Farm, Bennington, Vt.

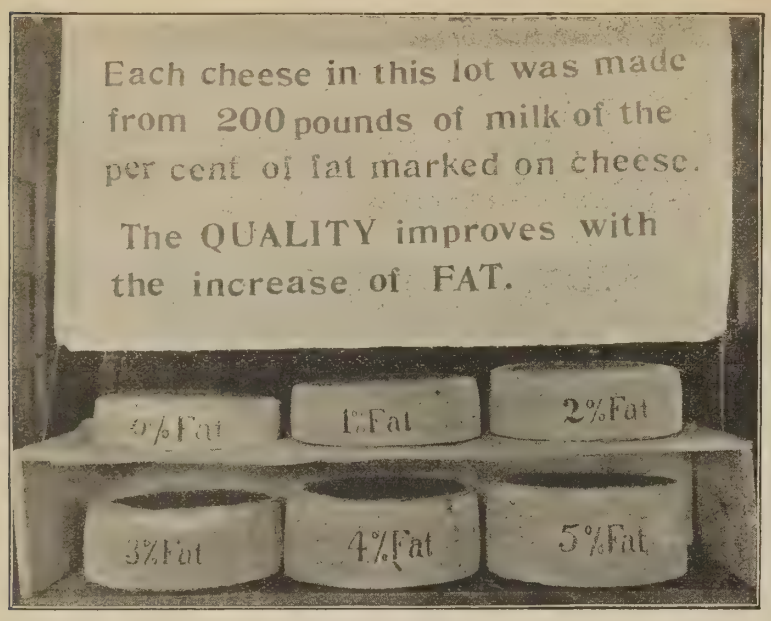
Wanted—Ten Guernsey Cows. Send particulars DUNHAM CO., 1392 Amherst St., Buffalo, N. Y. 9-2

Wanted—At our dairy, near here, a thoroughly posted dairyman and milker, for position of foreman. Wages $35.00 to $40.00 per month and house rent free. Address, with full particulars of experience and references, MERAMEC HIGHLANDS CO., St. Louis, Mo. 9-2

Haunts in the Wild Woods and gay places for summer outings. Either or both, can be found along the lines of the Chicago Milwaukee & St. Paul R'y in Wisconsin, Minnesota, Northern Michigan, Iowa and the Dakotas. Among the many delightful summer resorts are Delavan, Waukesha, Oconomowoc, Elkhart Lake, Marquette, Madison, Kilbourn, Minocqua, Star Lake, Lakes Okoboji, Spirit Lake, Clear Lake, Big Stone, Frontenac, White Bear and Lake Minnetonka. In the north woods of Wisconsin, in the forests of Northern Michigan and Minnesota, and in the far stretches of the Dakotas true sportsmen can fish and hunt to thier heart's content. For pamphlet of "Summer Tours," and "Fishing and Hunting," apply to nearest ticket agent, or address with two cent stamp, GEO. H. HEAFFORD, Gen'l Pass, A't., 555 Old Colony Building, Chicago, Ill. 9-3

For Sale—Holstein-Friesian bull calves of choice breeding. Will sell cheap if taken soon. For particulars address, JOHN SHUGART & SON, National Military Home, Ind. 7-6

Position Wanted—By competent butter maker. 7 years experience in separator creamery. Can handle 9,000 lbs. of milk daily alone. Can keep books if wished. 6 years with one employer. Address L, care Hoard's Dairyman. 8-tf



Hermanville Tamworths, Cross-heds, etc. J. A. MACDONALD, Hermanville Farm, P.E.I., Can. 32-52

An Entire Carload—Of high graded Jersey cows and heifers are in my hands for sale immediatley. F. H. MERRELL, Portage, Wis. 52-tf

For Sale or Rent—The Portage creamery, Portage, Wis. Immediate possession. Liberal terms to good party. WILLIAM FULTON, Prop. 5-tf

Relation of Fat to Cheese Production.

[Press Bulletin.]

The cheese represented in the above cut were made by Mr. Decker, instructor in cheese making at the Dairy School of the University of Wisconsin, to show the influence of fat upon the production of cheese.

As the same amount of milk was used in each case, the difference in size is due entirely to the difference in per cent of fat contained in the milks.

The improvement in the qualtity of cheese as the fat in the milk increases is nearly as marked as is the increase in size.

The proportional loss of fat in the whey is less from rich milks than from poor milks, showing the greater economy, when properly handled, of rich milks over poor milks for cheese production.

These statements do not apply to milk to which cream has been added.

The pooling of milk, by weight alone, in cheese factories is as unjust to the producer of rich milk as it is in creameries. Careful tests conducted at a number of experiment stations confirm the above results and show conclusively that the per cent of fat is as true a measure of the value of milk for cheese production as it is now universally acknowledged to be for butter.

S. M. BABCOCK,
Chief Chemist to the Wisconsin Agricultural Experiment Station.

Note and Comment.

Ohio Maple Sugar.—The Growing Demand for Cream. Its Effect on Prices.

ED. HOARD'S DAIRYMAN:—After twenty weeks wandering up and down the states, east and west, in attendance at the institutes and conventions, we find ourselves once more at home and find it a pretty—in our opinion—good place to be at. Although it is now the 8th of the month, there is a good deal of winter lingering in the lap of spring, and maple sugar making is in full boom; and so little warm weather has there been, that the sugar is about as fine as in middle March. As winter dairying is the thing about here, we are literally possessors of "a land flowing with milk and maple lasses", both selling at about the same price.

The great northeastern dairy section of Ohio is also the greatest maple producing section of like size in the U. S., and in the spring, to care for the dairy, go to creamery or train with the milk, and look after a sugar bush, does not give the farmer much time to look into the needs of the Phillipinos; consequently he is content to let Admiral Dewey and Otis look after our far away wards (?); though we did hear a man say recently that if we could get our newly acquired citizens of the Pacific sea to eat a few U. S. skim cheese, by the time they got it digested, they would have a pretty comprehensive idea of the stable character of one American industry, at least.

In the particular section in which the writer lives, a new element has appeared to disturb the old order of things, which was to let one man set the price of milk, month by month, and then all the rest pay his prices. There are really two factors in the innovation; the rapidly increasing demand for cream from Pittsburgh, and Cleveland, and also noticed in a degree in the smaller cities like Akron, Youngstown, and those of lesser size, and creameries by the dozen are now having to hustle to supply the demand.

As this cream is not dependent upon Elgin for butter prices, or Little Falls for cheese quotations, the price for milk for cream, and for cheese or butter has been parting company gradually, and this spring in this section they are not "keeping company" at all, and this is the disturbing element in the matter.

The creameries, some six or more of them in this immediate section, are paying $1.10 per 100 pounds for milk and the cheese factory men were paying $.80, but for April advanced their prices to $.90.

To get milk in the vicinity of some of the cream shipping concerns, the cheese men are having to pay $1.10, which is not pleasant to patrons, at distant concerns, out of cream circles, to be obliged to take up with two and three cents less per gallon.

It is disturbing the city milk buyers, who are buying 8½ pounds for eight cents, the shipper paying fifteen cents for transportation for 85 pounds, so nets him only a trifle over eighty cents per 100 pounds.

It was said that the cream business would be speedily overdone, but one cream dealer had an order, in addition to all his previous trade, of about 60,000 gallons, which compelled him to go out and lease cheese factory concerns, and turn them into cream concerns. This only adds to the interest, and there are now some pretty long milk routes springing up right through cheese territory, to deliver milk to cream shippers.

***

The building of six, and irons being laid on four more electric lines, radiating from Cleveland, most of them running out fifty miles into dairy territory, not reached by the steam lines, is having its effect in more ways than one on the milk trade of the city. The freight rates of the trollies are much lower, the car stops anywhere there is a can of milk in sight, and much the same way, where market stuff is carried. Anything that can be carried by hand, and is accompanied by the owner, goes free, and it is having an economic side in the farmer's methods, and is already producing marked changes, and seemingly to his advantage, though the country produce dealer is calling out that he is being "pinched," and the country merchant is having troubles of his own.

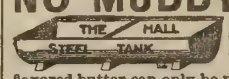
Northern Ohio is in a period of rapid transition. There is the great growth of Cleveland, where the great ore and steel industries seem to be rapidly centering, causing a rapid change of population incident to the re-adjustment of our industries; trolly lines are built, building, and being projected in all directions; no place in the United States is so netted over with telephone lines, connecting farm and village in like degree; dairying and its methods are being changed, and re-systematized; even the school methods are being revolutionized, and in a score of towns on the Western Reserve, the district school has gone, and the centralized graded and high school has combined all in one building at the township center, and is up with the times in educational porgress. All more than of passing interest.

***

My travels in the different states the past winter, were most pleasant routes, and in the dairy sections the interest was good; but I am compelled to say that the inquiries were more along the lines of cheaper produced dairy rations, better combinations of foods, than about better cows, for along the latter there should be a far greater "hungering and thirsting after dairy wisdom." The two should go together.

The dairy banner should have inscribed upon it, "A better cow, more cheaply fed." Oats, peas, corn, silage, soiling crops, silos, barns and how to ventilate them, have been inquiries constantly, and evidently made with purpose to be benefited by them. The silo question seems one of the topics that is perennial, freshens yearly, and is always to be talked over, and up; always just opposition rumors enough in the air to start a fresh breeze of testimony in its favor.

In my opinion, as many, if not more, silos were built in 1898 as in any other one year before, and by the tide of letters I get from all sections, I should say that 1899 was to be a record breaker. A new feature that is commending the silo, is the testimony of those who are summer feeding silage in lieu of soiling crops. The trend of this testimony is to the effect that it is a better supplementary ration, takes the place of the summer grain ration, holds the cows up to their milk better because constant in amount and quality, which a variety of green crops at all stages cannot be. Silage is always at hand and, more, a pretty sure crop, for it now seems demonstrated that corn planted on sod land, cultivated shallow so as not to destroy roots, and frequently enough so as to keep a dust mulch on the land to prevent evaporation of soil moisture, will, nineteen times out of twenty, bring a full crop of corn, if the summer fall of rain is not abundant, even in the drouth territory. This puts the dairyman in a position to be independent of mills, or millers' combines; brings feed from land to cow direct, without paying duty to elevator, broker, freight, tolls, commissions, and adulteration in transit, and must always be a great factor in profitable dairying.



I was greatly impressed with the sound, practical doctrine, preached by the institute force of New York, from governor, down. Always instructive, helpful, and, as I saw it, up-to-date. The help of Profs. Jordan, Roberts, Van Slyke, Wing, Smith, Hall, from the station crews, was always timely and instructive. No more helpful book was ever issued than that of Prof. Stone, of Cornell, Bulletin 154, wherein he has figured out the elements, and their proportions, in all the cattle foods, and forages, green and dry, from 1 to 20 pounds, so that if a man will weigh the amounts of food he is feeding his cow, he can, by turning to this book, figure up the amount of protein, starch and fat, without getting confused, or in the end blessing(?) the man who invented feeding tables and balanced rations. If the farmers will practice half what they have heard the past winter, New York will soon regain her old time prestige of being the banner dairy state, and Iowa will have to play second tin horn in the dairy orchestra.

***

It was thought to be a great innovation in New York dairying when the milk trains of Philadelphia and New York came up into and beyond the Binghamton settlement, but this winter, milk is being sent from Northern New York, close to the St. Lawrence river, and cream as well. One firm, that of H. E. Cook & Bro., of Denmark, is shipping cream to New York city, red hot, starting it at a temperature of 160°, sending it in jacketed cans, and with the best results—a plan adopted by the French Bros. of Cincinnati, O., last year for their long distance cream, in hot weather.

Up in this northern region, vast amounts of fancy and high priced cheese is made, the full equal of any imported from Europe. The demand is fast increasing, and additional

concerns are being organized to supply it, though it is doubtful if the patrons realize the full importance of this new creative industry. JOHN GOULD.

Ohio.

DAIRY RETURNS PER COW IN MAINE.

The returns from twenty creameries have been taken, and, like all previous attempts at the taking of a cow census, the figures disclosed show a rather low state of profitableness. The milk and cream of 22,680 cows were consumed at these twenty creameries, for which $682,000 was paid. This makes an average return of $30.60 per cow. In some dairies as high as $50 per cow was paid, in others as low as $20 per cow, making the difference, as one can see, over 100 per cent. Wherever any intelligent attempt is made to get at the real state of affairs with creamery patrons, it is always found that there is difference enough in cow profit between them to show that indifference and disregard of good dairy teaching is a losing business.

It is the farmer in Maine, and every other state, who makes his cows earn only $20, who is keeping the dairy industry down. As we have said before, there would be no low prices if the product of these poor cows, and poorer owners, could be kept out of the market. It is the cows that make butter at a loss that overload the market with a surplus.

Another View of Milk Trusts.

ED. HOARD'S DAIRYMAN:—In your number of 3rd inst, you give the views of a farmer on the milk trust. For all but the final conclusions I agree with the writer, who makes matters very plain. The trust is the logical outcome of a more correct conception of economics put into practice, and thus the trust often greatly serves the consumer. The trouble, that it is not yet an unqualified good, lies in the fact that to-day this concentration of management, and this economy of labor (production) is practically applied almost entirely by the wealthy for the sole purpose of adding to the wealth—that is, in the matter of industries.

Their object distinctly is not "to serve", but "to enrich themselves", making the most of their special opportunity. That they incidentally and accidentally do "serve" a *portion* of the people is quite a secondary consideration, all their asseverations to the contrary notwithstanding.

The "rich" see that competition means fighting, war; and war entails suffering and death, and thus, in their shortsightedness, and in spite of their shrewdness they attempt to overpower competition by monopoly. This is just the way a brutal man abuses a nervous cow. He licks her into subjection, and opposing brute force to brute fear, thinks he has vanquished his cow and is ruler in his domain. What are the facts? By his unbridled choler he has injured his manhood, he has caused himself the heaviest of hard work and must ever after maintain a strict watch, for he is dealing with an enemy sure to catch him unawares. Besides, he has a cow that will give less milk of a poorer quality than her capacity calls for, and she is more liable to attacks of nervous diseases and accidents.

Set in juxtaposition the case of the "gentleman" (clothes and calling have nothing to do with this qualification of man), who has gained the confidence, and affection of his cow. Words are unnecessary to illustrate these extremes. The nervous cow is a good thing if rightly handled. So also is the Trust.

Supposing that instead of Leiter, the consumers of Chicago consolidated themselves into a body and followed the plans of the combine; why, they would benefit themselves far more than you ever could or would. But further, let these combined citizens make common cause with their employes from the first to the last, treating all their help with all the care and cunning they give to their finest cows, only giving them accordingly more consideration, as a man is higher than a beast.

Would not the result be proportionate with those noted in the case of the cows? Municipal ownership in Glasgow as in American cities, answers, "Most certainly!" Faint hearted ones and doubting, say, "As yet it cannot be, the time is not ripe, it will take generations." Blind they are to the fact, that there are numbers of men in our midst today who saw the first railroad built in America; and but few of us who read this paper that have not seen electricity first used as motive power or for lighting purposes.

Abolition was scarce dreamed of at the opening of the war. "Men shall dwell together as brethren," and though we go on deceiving ourselves by being "hearers of the word only" that decree has gone forth and *shall be accomplished.* Let those who dread advance struggle as they like, the change is even now upon us.

We may languish for "grandad's" cows or fear the deluge of milk, visions and nightmare cut no swath. Open your eye to the fact that the trust, the pool, the monopoly is as far ahead of the one-horse concern as the binder is of the cradle and you will soon find the means to get on the "inside", and like sheep, the rest will follow.

Then will we have a production managed along lines of true science, and America, this grand country of sunshine and possibilities, will have grain and milk for all her children. Rent, profit and interest will no longer suck the life blood from the American toiler, and the whole fruit of his labor shall be his. When the American Sampson slays his lion, (the trust for greed) he shall surely find honey in the carcass. D. F. B.

Ruskin, B. C.

To Prevent Silage From Spoiling.

ED. HOARD'S DAIRYMAN:—There appear to be numerous complaints about silage spoiling in a square silo, and for the benefit of those, like myself, who are obliged to build a square one, I would like to give the experience of a neighbor of mine, who last year built one 15x18 feet and 20 feet deep. He made it one foot smaller at the bottom, drawing in each side and end three inches, and as the silage settled, it became so tight in the corners, that he has not lost a pound.

I used the balanced ration you were kind enough to make out for me, and my cows are doing better. E. M. B.

Croton Falls, N. Y.

Land Plaster

NATURE'S FERTILIZER. The great stimulating element to the growth of cereals, plants, and all vegetation. In use for over one hundred years. The good results obtained from the use of **LAND PLASTER** have only to be understood to make it fully appreciated.

Michigan Land Plaster

IS NOT EXCELLED IN THE WORLD.

Farmers of WISCONSIN and MINNESOTA can obtain Fine Fresh Ground **Michigan Land Plaster** by the car load of **15 tons** and upwards, loaded on the cars at the Mills, Grand Rapids, Mich.

In bulk	$ 1,00 per ton.
In American A grain bags	2.45 " "
In Stark A grain bags	2.70 " "

Shipping via car ferry at Muskegon a freight rate of **5 cents per 100 lbs.** can be obtained to Milwaukee, so that the plaster can be shipped in bulk and the expense of bags saved if desired. The railroads make special plaster rates from Milwaukee, which consignees should arrange for in making up a through rate to their station.

We have a large stock and can ship promptly at all times.

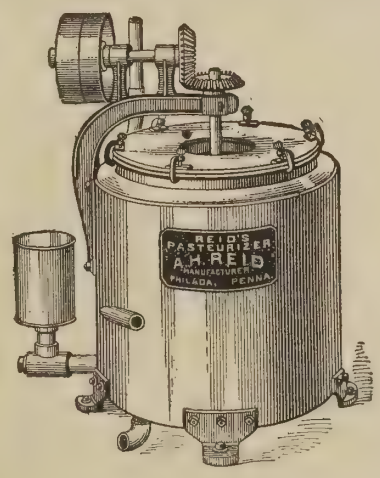
AN ERA OF

Better Machinery



Hard times and rattletrap machinery are of the past. Creamerymen have found out that it is more profitable to own a good

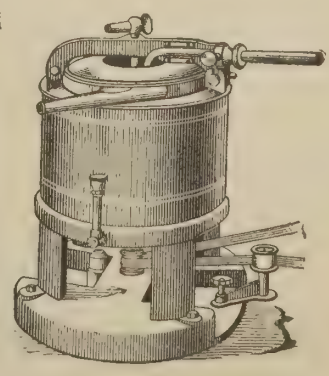
STANDARD BABCOCK TESTER

that will last for twenty years than it is to buy one of the ordinary, noisy kind, that must be replaced every year or two. The Standard has a cast iron frame and cover, a steel spindle and brass bottle holder. **It is well built and is acid proof.** The new book of Farrington and Woll, on Milk Testing goes with the machine.

Send for Catalogue No. 85.

Elgin Manufacturing Co., Elgin, Ills.

Is Pasteurizing A Success?



Ask the creamerymen who are making pasteurized butter and the butter men and retail dealers who are selling it. Ask them how it compares with other butter—if it doesn't command better prices—if it isn't preferred by consumers. Read what Philadelphia's largest commission merchant says about the rapidly growing demand for pasteurized butter:

PHILADELPHIA, March 1, 1899.

Dear Sir:—In reply to your inquiry regarding the merits of pasteurized butter, would say that we are receiving it from a number of creameries who have adopted your system of pasteurization, and the only difficulty we find is, we are unable to supply the demand. Pasteurized butter makes its own way in the market and commands a far better price than the average good creamery butter. We are always ready to pay a good price for pasteurized butter and buy as much of it as we can get.

Water and Market Sts., Philadelphia. JOHN JAMISON.

The only machine that has satisfactorily and practically solved the problem of pasteurization is the

REID PASTEURIZER.

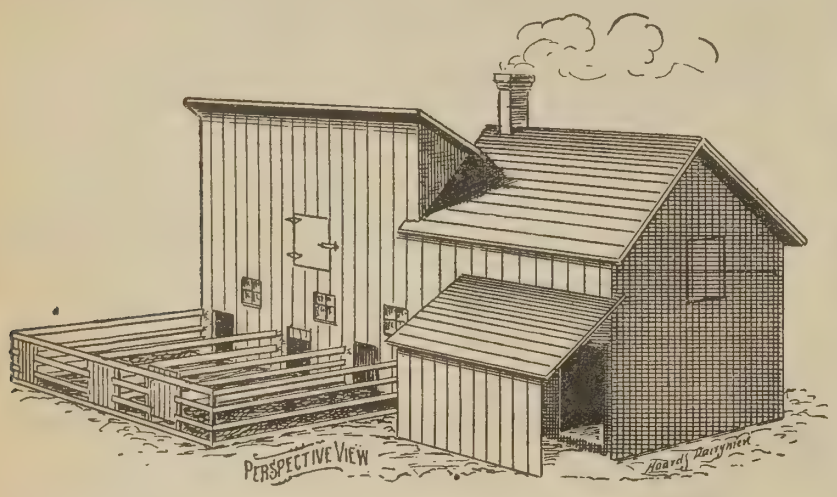
A. H. REID, 30th and Market Sts., PHILADELPHIA, And CEDAR RAPIDS, IOWA.



A PLAN FOR A HOG HOUSE.

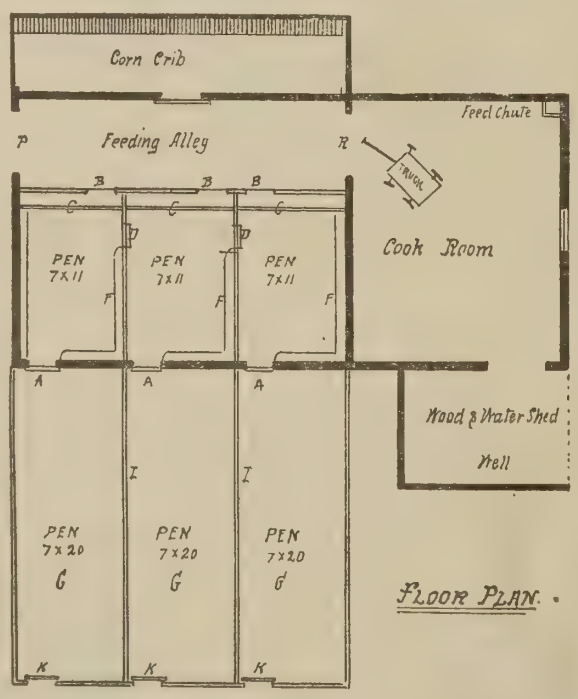
There is much interest this spring in plans for hog houses. In response to inquirers, we publish the plans and description of the house used by that veteran breeder, Theo. Louis. It goes without saying that a hog house, planned by one with so wide an experience in hog raising as Mr. Louis, must be both practical and economical, and as such we recommend it to our readers:

ED. HOARD'S DAIRYMAN:—The cut accompanying this article gives an exact representation of the house that we have in use, as protection for sows against overlying pigs.

G. G. Front yard to hog house, with a permanent fence built 20 feet distant from building. A drive gate is left on each side of this yard, and the yard itself is divided with movable fence panels made out of common fencingof 14 foot and 7 foot lengths, bolted together in the lap, and held in place by two 2 x 4s on each end forming a slide. This forms, in breeding time, a yard for each sow 7x20 feet. When not needed, panels are removed, and have yard free as a drive way for wagon to gather manure.

K. K. are up and down slide gates 2x2½

save that the roof is here made to slant altogether one way—to the rear. We consider that an improvement on our own, but could not avoid this, as we have on the north side (as will be seen in ground plan) a corn crib attached, and, therefore had a hip roof to gain pitch. It is preferable to have no water shed from roof in yard to soak them and create, in rainy seasons, an unhealthy condition, besides causing much loss of valuable manure.



The dimensions are as follows: Width 16 feet, height should be no less in front than 14 feet for reasons hereafter given; length of building (of hog house proper) depends upon the number of hogs to be kept; width of feeding alley 5 feet; size of pens 7X11, size of doors (A) 2X3 feet. On each side of door is a studding, between which, the door slides up and down. Underneath the upper floor is a home-made pulley over each door. A cord passes through this from door to alley, so that door can be operated to close or open at will.

B B are doors, the height of partitions, and are 20 inches in width, hung on hinges. These are fastened to a 2X6, standing flat-wise to the alley, and supported upon floor joists, one on each side of door, to which partition boards are nailed. Partitions are 3 feet 10 inches in height. The door is fastened with a stick or bar made out of a 6-inch board, a little above the center. This proves effective.

C C are troughs made out of 2X6 and 2X8, whole width of each pen. The door extends down to this only, and not to the floor, and swings above a threshhold nailed to trough and partition. This avoids climbing over partitions, and if a scale is arranged in alley, it is but an easy matter to educate one's self in the art of feeding, by passing hogs out and in.

D D are doors to slide up and down, supported by two 2X4's in each stall, so as to transfer sows, or to leave open, and close one of the outside doors, and use one pen for sleeping, the other for feeding. This makes separation possible in winter, larger and smaller sows to be fed together.

F F are fenders in each pen, securely fastened, made out of 2X6 or 2x8, and set from 8 to 10 inches from floor, fastened edgewise

feet, fastened with pin above, or to be raised so only pigs can enter.

The lower room in hog house is 6½ feet in clear between joists. The upper floor is supported by using 2x6 three and four feet apart and floored with inch boards, simply nailed so as to avoid any danger of slipping. The loft is used for bedding and filled each fall after threshing. This keeps the house warm from above, and bedding is always dry and always plenty so as to be used as an absorbent when cleaned out of pens.

Over each pen and directly above the fender, is a board so fitted as to let down straw, and serve as ventilator. The loft is filled through door opening into yard, and these doors should correspond in number to length of house. To ascend to loft from inside of alley, a permanent step ladder is adjusted from the top of the partition in a slanting position near center of building with trap door to close. The slop boards on troughs through partition are nailed to troughs and are the whole length of trough with the exception of doors B B.

Each pen has a half window of 7x9 glass, directly over the fender, which slides on girt sideways, so the house is well lighted, and warm sun rays go in each apartment, and one is not groping his way in darkness.

Size of feed and cook house, 14x16, with 12 foot studding—14 would be better. The loft is used for ground grain and is divided into two bins. This floor needs to be well supported with 2x8 joist. Grain is elevated

through door in end, which comes down level with floor. Grain descends through feed chute. Chamber is reached with a ladder adjusted between two joist in centre of building under the upper alley way. The ladder is hung on an iron rod which goes through both joist and ladder and is swung up between joist when not needed.

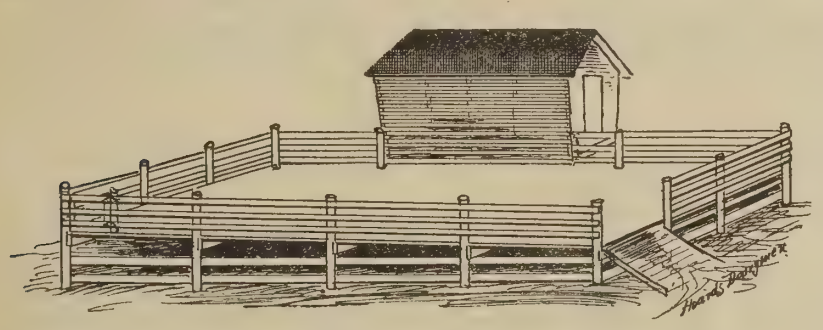
The opening from cook-room to shed is provided with a slide door. Truck is a simple platform with large double table casters for wheels, and will hold four large pails or a tub. It saves time and labor. P, door at end of alley. Hogs may be loaded here by having a step board. R, door into alley.

VIEW OF CORN CRIB

If a corn crib is to be attached under the same roof, as shown in diagram, it should (in a northern state) be no wider than 3 feet at the bottom and 4 at the top, as the side wall of hog house would prevent circulation. Ours is full length of hog house and holds 2,000 bushels of ear corn. It is slatted up and down; and holes left every six feet, by nailing strip on slats firmly underneath where they are to be cut.

When put back in place the upper end of slats rests against plate and horizontal strips against uncut slats inside; when crib is filled to its full capacity with corn, they can not be opened from outside. The doors on inside, opening into alley are slide doors. There are two in 70 feet.

The foundation is a stone wall, and should be at least two feet high, one foot beneath the surface, so that hogs will not undermine it, laid in lime mortar, but at intervals boxes four or five inches square should be inserted next to the sill, with open wire netting nailed on the inside so as to permit circulation of air. During the season when cold drafts will be injurious to sows and pigs, they can be closed, but when opened in summer, will keep it dry and healthy.



The sills are 2 x 8 doubled by breaking joints and coal-tarred. Ours are now nearly eighteen years old and in good condition. They too should be bedded in mortar. The joists are 2 x 8, three feet apart and cross-bridged in center. The floor is pine plank all of one width, so they can be replaced in front of troughs, where they give out first.

If kept clean, as they should be, their duration is at least eighteen to twenty years. I prefer them to cement floors and to boards on cement, as they become contaminated beneath and are always damp. The floors run lengthwise of the building.

The frame is built of 2 x 6, seven feet apart, the width of pens. An inch board nailed to these studdings to receive the upper joist; and girts of 2 x 6, four feet apart, inserted to hold siding. The building is double boarded with wide boards, and had paper been in vogue at the time of building, we should have had the paper between.

The entire structure, eighty-six feet long, with lumber at $9.00 per 1,000, shingles at $1.50, stone furnished by ourselves and also most of the labor, required a cash outlay of $165, and thousands of pigs raised in it never told the doleful tale of contamination, and we still think it a place of comfort, more so when winter approaches; a source of economy of feed and labor.

FOREIGN BUTTER MARKETS.

Dowdall Bros., of Manchester, England, send us the following "Butter Review" It is interesting from several points. It shows that the dairymen in this country are not the only ones to suffer from unseasonable weather. That frost and snow plague the European as well as the American dairyman. As the market immediately shows the effect of such weather, the relation of cold to butter fat production must be also as important a factor to the European dairyman as in this country. We note that Russian, Friesland, and Argentine butter competes with the French, Australian, and New Zealand article—an interesting comment on the cosmopolitan nature of the English butter market.

The bitterly cold weather, with snow storms, which has prevailed for the past week, has steadied markets, which had been inclined to droop, and a firmer feeling began on Wednesday, which has since hardened into a very good demand for butter to-day. In Denmark, very severe winter weather set in just as they were preparing for spring. Snow is covering the country, and the windows are blinded with ice, even in heated rooms. The frost now will have the effect of retarding vegetation very considerably.

British markets were fairly firm at unchanged rates, if not slightly lower than the previous week. Both Newcastle and Manchester had increased arrivals, and although not quite brisk, cleared fairly well, the tendency of buyers being to act cautiously Copenhagen had sufficient orders to cover supply and justify the official top quotation being unchanged. The Danish quotation is still 5 kroner higher than last year at the same time. The Hamburg market is firm at unaltered top price, but independent f. o. b. prices are 2 shillings dearer. It is said that in Ireland, grass is several weeks behind, because of recent frosts, when there was no snow to protect the soil. Yet, advance lots of creameries have been marketed this week, and show wonderfully good texture and flavour. It is always refreshing to sample these butters in the Spring. Russian and Finnish butters are on the increase. Frieslands show excellent quality. Imports of butter for February are in excess of last year, the United States contributing 24,899 cwt. more than in 1898 New Zealand also sent 5,199 cwt. more, but Victoria sent 10,254 cwt. less, and France 7,777 less. A heavy shipment of Argentine butter arrives next week. The weather has turned milder, wind changed, with heavy rain. In margarines and mixtures, fair business is doing. Margarine arrivals via Hull, 11 427 packages, and via Grimsby, 5,845 packages.

Steam in Dairy.

How a Dairyman Uses It.

ED. HOARD'S DAIRYMAN:—It is indispensible. Here follows what I do with a two horse boiler.

1. It runs an engine, and the engine runs a squeezer combined churn and worker, and a grindstone.

2 A Little Giant separator.

3. A sterilizing outfit, that can sterilize cream as it comes from separator. Also used for heating milk, etc.

4. A steam connection, which runs up through washing table, over which we turn cans, etc., for steaming.

5. A connection with two movable joints which can be lifted into a can, pail, or any other vessel for heating water.

6. Turn steam into a coil of pipe in cream ripening room.

7. Can turn steam into my house heating system, to augment that, in case of emergency.

8. When I find my water pipes in adjoining kitchen frozen up, I attach a long hose pipe, and in five minutes Jack Frost's work is undone.

9. Last, but by no means least, a connection runs into a tank of water, which can be made scalding hot in five minutes.

I use five cream cans, each holding ten gallons. These are made of crockery ware and lined with a chemically prepared enamel. They are set in a tin jacket, air tight, and water is let in through a spout and pipe, with an overflow on opposite side. Hot water is kept flowing through till cream is warmed to desired temperature. In hot weather, when I desire to cool the cream, cold water is kept running through same pipes.

Mr. Wheaton's Canadian Dairy Notes.

Spring Cheese and Butter—Looking Forward in the Dairy Business—Money Making Cows—Building up a Herd. The Scrub Bull—Irregular Breeding—Canadian Dairy Schools.

ED. HOARD'S DAIRYMAN:—Notwithstanding the advice given on all sides, and the repeated warnings against making early spring or fodder cheese, we hear of many factories doing so. Of course it is hard to get people to adopt a line of practice when they feel that in doing so they are losing a temporary gain.

Such is the outlook for the cheese trade at the present time. That early cheese is likely to bring 10 cents or more per pound, and with a good demand at that. With this prospect before them, it is difficult to get dairymen to keep on making butter till the grass season opens up.

It is a question, however, if calves are to be raised, whether it will not pay better to make butter at 19 or 20 cents per pound, and have the skim milk returned, than to make fodder cheese at 10 or 10½ cents per pound.

We are all a little too much inclined to seize hold of the smaller thing which is at hand, rather than reach out for the more comprehensive plan which would make things better for the future. The seeming rush on the part of factories to make early cheese, while perhaps giving the dairymen a good return at the time, may, before the season is over, cause an increased supply that will bring the price back to what it was last year.

Speaking of working and living for the present, we question whether the half of our dairymen ever look beyond that point in connection with their business. How often do we see dairymen going along, year after year, with the same old unprofitable cow and the same old careless and slipshod methods of feeding and caring for them.

Such persons must live only in the present for they never act and plan as if they wished the future to bring better results than the past.

In this dairy business it is not the man whose cows give a large flow of milk in June when the grass is plentiful, and then dry up in August, because he has not seen far enough into the future to sow some peas and oats or other grains to provide supplementary feed, who makes the most money out of dairying.

The dairyman who is making money out of his cows every year, and every day in the year, is the one who looks ahead and so plans for the future, that his cows have all the good, succulent food they require at all times, and are given that care and attention necessary to make them produce to their utmost capacity.

This latter may be an ideal condition, but still there are many dairymen in Canada and elsewhere, who, from definite plans formed, it may be years ago, and which they have followed intelligently and wisely, are today reaping a rich harvest.

There is one phase of the dairy business, which, if the dairyman does not plan for the future he cannot possibly hope to succeed in, and that is building up a dairy herd. It is really a matter of surprise, considering the amount of preaching and teaching that has been given on this subject, to find so many poor and unprofitable cows, even in the older dairy districts of this country. We may well ask, why is this?

If a dairyman reads any kind of an agricultural paper, attends an institute or dairy meeting, or makes any comparison of his own cows with his neighbors, he must surely learn enough to know that there are good cows and poor cows. And knowing this, why don't he get rid of his poor cows, and keep only those that are profitable?

The answer to this problem is, we think, that a large number of dairymen live and work only in the present. To breed and build up a good dairy herd, a dairyman must look ahead. He must have his ideal dairy cow in his mind, and bend all his energies and skill in the direction of producing, or reaching up to that ideal. This cannot be done in a day. With the kind of cows that many of our dairymen have at the present time, it may take a generation to reach the highest point in the way of a dairy cow, and then with some cows as a foundation stock, such a thing is almost impossible. But still the goal is worth reaching up to, and if the dairyman's cows are of such an inferior kind that it would be only a waste of time to attempt to build up a good dairy herd from them, then the whole lot should be discarded, and better ones got as a sort of "starter," from his more successful neighbors.

But nearly every dairyman will have some good, or fairly good cows among his herd. Then let him take these and breed them to a good dairy bull, whose ancestry have a record as large milk producers. Such an animal can usually be found in every dairy district, if a little trouble is taken to look for him.

One of the drawbacks, and a positive check to good breeding, is the "scrub" bull. That kind of an animal that would be ashamed of his ancestry, if brought to light, and who owes his existence to the fact that there are plenty of dairymen and farmers who require his services because they are cheap.

This is the type of animal that many dairymen take even some of their best cows to, and expect to raise a good cow from his progeny; just because there are some good milking qualities on the maternal side of the combination. But it is absurd to expect good results from such a line of procedure.

To raise good cows, a regular and systematic line of breeding must be followed. Particular attention must be given to the sire, and he must have more reason for his existence than being merely a "getter of calves." There must be continuity in the system.

It will never do to jump around from one line of breeding to another, without any good reason for doing so. One of the reasons why so many fail to produce good stock, who seemingly start out right, is that they do not stick to the one line of breeding long enough to make a success of it, and obtain permanent results.

A wise selection, a continued effort, and an intelligent application of methods are essential to all good breeding, and to none more than breeding good dairy cows.

The Provincial Dairy School, of Guelph, closed its seventh session on March 25th. There has been an attendance of 115 students, during the term, the majority of whom remained for the three months' course. Among this number were sixteen ladies. Forty-four candidates were successful in passing the examination, and in obtaining certificates for general proficiency.

The new dairy school building, at Sussex, N. B., is completed, and the school in full blast. The attendance is now twenty-five, with more to follow, which is a pretty good showing for a comparatively new dairy district.

A new school has been started at Woodstock, N. B., which is in the western part of the province, and in the center of the best farming district. These two schools should give ample accommodation to the dairymen of the maritime provinces.

The cheese market continues strong and active. Last week (April 8th) holders of old stock, held at Montreal, were asking as high as 11½ cents, with the prospect of probably 12 cents being reached before the season is over. The English buyer could have had this cheese a month ago at under 10 cents but he would not accept, believing that there were large quantities on this side still to go forward. He had not, however, summed up the situation carefully, and consequently will have to fork over a cent or two more a pound, in order to get the goods.

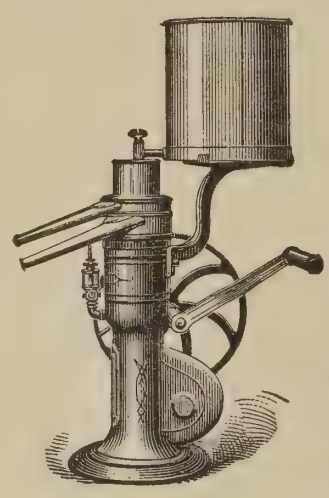
There are comparatively few cheese in store on this side, which makes it all the clearer, that before the bulk of the new goods reaches Great Britain, there would be very little old stock in its way.

The creamery butter situation, on the whole is weaker, and prices during the week dropped from 1 cent to 1½ cents at Montreal from top prices, 19½ to 20 cents being the ruling figures for choice fresh creamery. Should the bulk of the combined factories that are now making butter change to cheese making, there may be a reaction in the butter market that would mean better prices. There is not so much butter put into cold storage, as was the case a few years ago, which makes the butter trade more of a hand to mouth business.

J. W. WHEATON.

Toronto, Canada.

Always Use the BEST.



The temptation to try a cheaper article in manufacturing high grade goods is such that the experiment is often undertaken and results generally in producing an inferior article.

High grade butter needs the best of appliances and skill and particularly the best Color.

WELLS, RICHARDSON & CO.'S IMPROVED BUTTER COLOR

has maintained its reputation as the best. It is always reliable and gives the true June shade.

Inquiries as to Acid Test for Cream—Salting Butter in Churn.—Growing a Balanced Ration.

ED. HOARD'S DAIRYMAN:—I am making butter and want to know what and how to use that acid test I see mentioned in the DAIRYMAN for testing cream, to know what temperature to ripen at, when to churn and what temperature to wash at.

I have a U. S. separator and Davis swing churn, also Eureka worker, but am going to try salting and working in the churn tomorrow as mentioned in the DAIRYMAN last week.

I don't understand about what to grow to make a balanced ration. I have corn stover and corn and cob chop. Now will oats and peas make a balanced ration without buying any kind of feed? Are they to be threshed and ground together and is it Canada field peas that is meant?

I am putting in steam to run our dairy machinery and do the washing. I think that will be just the thing.

My cows are poor compared to those mentioned in the DAIRYMAN but I am trying to get better. I have a mixed Jersey and Guernsey bull which I am breeding from.

Do you think I can make it go making fifty pounds a week from ten cows, getting one cent above quotation, paying a hired man $12 a month and giving one third as rent for the farm? J. W. S.

Quakertown, Pa.

The writer of the above is one of those young men who are starting in right and will be pretty sure to come out right. He proposes to make his brain help his hands, and in whatever business men engage only those who subordinate physical force to mental force gain the highest rewards. If our young friend will address a letter to the Wisconsin Experiment Station, Madison, Wis, asking for h copy of the bulletin which deals with the acid test for cream, we think he will get more and better information on the subject he inquires about than it would be possible for us to give in reply here.

We do not remember having noticed any experiments made with salting butter in the swing churn. We cannot say that it would not be successful, but our impression is that this method is only practicable when some form of revolving churn is used. We would be glad to have J. W. S. report the result of his experiment with the swing churn.

We very much doubt whether it is practicable on the average farm to grow a sufficient variety of crops to make a profitably balanced ration. One can frequently sell corn and oats or some other farm crop and purchase some of the by-products or millfeeds with great advantage. We think the ideal ration is composed of silage, clover hay or oat and pea hay, a little corn stover, corn and cob meal, bran and gluten feed or cotton seed meal. In the absence of silage or roots we would include in the list of grains, a little linseed oil meal. The following formula will show about the proportions that we think it necessary to feed where there is neither silage nor roots:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
12 lbs. oat and pea hay	10.18	.72	5 19	.18
10 lbs. corn stover	5.95	.17	3.24	.07
4 lbs. corn cob meal	3.56	.26	2.52	.14
2 lbs. bran	1.76	.25	.77	.06
1 lb. oil meal	.91	.29	.33	.07
1 lb. cotton seed meal	.92	.37	.17	.09
Totals	23.28	2.06	12.21	.61

The above should be considered the minimum allowance. It should be increased by adding more of the oat and pea hay if the cows will eat it, and if not, increase the grain allowance for the cows which have the capacity to make good use of it.

Rennet Test Questions Answered.

ED. HOARD'S DAIRYMAN:—Will you please answer the following questions?

1st. At what rennet test (Marschal's) would you consider it best to set milk in spring and what quantity of rennet to be used per 1,000 pounds milk, in ounces? (Chr. Hansen's Dannish rennet.)

2nd. How long from the time rennet is added should the vat stand until cut.

3rd. How low rennet test would you consider it safe to take patrons' milk? Would you advise taking a patron's milk that would not run over two test, Marschal's, or how low?

Having had very good success in the cheese factory so far, yet I still look to HOARD'S DAIRYMAN for advice, and should be very glad to see more articles on cheese making.

Enterprise, Kan. A. H. D.

Mr. D., like a good many other cheese makers, is being mislead by the Marschal rennet test. The divisions on the Marschal cup may be the same in different pieces of apparatus, but the holes in the glass outlets are not alike. In fact they vary 150 per cent in size. The result is that with one cup the milk will curdle at the 1½ mark while with the same milk in another cup it will not curdle till it reaches the 3½ mark.

It is not intended that a maker shall go arbitrarily by the marks, any way. He should set his milk by the rennet test so that in two and a half hours from the time he sets the milk, he will have one-eighth of an inch of strings on the hot iron, and can get his cook or scald by that time. When he knows what rennet test is required to get the curd to work off in this length of time, he can ripen his milk to the same point each day and his curd will take acid in about the same length ot time. Knowing this, he can get a uniform cook, and a uniform cook means a uniform cheese.

Use enough rennet to curdle the milk at this ripeness at a temperature of 86 degrees in twenty minutes.

We would advise the use of the Farrington tablet solution as described on page 146 of the Fourteenth Report of the Wisconsin Agricultural Experiment Station. Most of the readers may not have access to a copy of this and will give a short description of the method as follows:

Get a package of Farrington tablets which can be procured of any supply house. Take a bottle, and for each ounce of pure water—soft water preferred—in the bottle, add one tablet. Of course, the water should be carefully measured. When the tablets are dissolved, the solution is ready for use. It should not be used after the day that it is made. Take a No. 10 brass cartridge and solder a wire handle to it. This is to be used as a measure. Take one measure of milk from the can and pour it into a tea cup Then take two measures of the solution and and add to the milk in the cup, and stir them together. If the color remains pink, the milk can be accepted; but if the pink color disappears, there is more than two tenths of one per cent of acid in the milk, and the same should be rejected. The patron cannot say that the maker is mistaken. The acid test tells the story.

Madison, Wis. JOHN W. DECKER.

SPRAYING FRUIT TREES.

The question of spraying fruit trees to prevent the depredations of insect pests and fungus diseases is no longer an experiment but a necessity.

Our readers will do well to write Wm. Stahl, Quincy, Ill., and get his catalogue describing twenty-one styles of Spraying Outfits and full treatise on spraying the different fruit and vegetable crops, which contains much valuable information, and may be had for the asking.

DID YOU GET UP WITH A LAME BACK?

KIDNEY TROUBLE MAKES YOU MISERABLE.

Dr. Kilmer's SWAMP-ROOT is the Great Remedy for Kidney, Bladder and Uric Acid Troubles.

By Special Arrangement Every "Dairyman" Reader to Prove For Themselves the Wonderful Merits of this Great Discovery, May have a Sample Bottle Sent Absolutely FREE by Mail.

Well people have healthy kidneys.

You are in no danger of being sick if you keep your kidneys well.

They filter your blood and keep it pure and free from disease-breeding germs.

Your other organs may need care, but your kidneys most, because they do most.

If you are sick, begin with your kidneys, because as soon as they are well they will help all the other organs to health.

The treatment of some diseases may be delayed without danger, not so with kidney disease.

Swamp-Root is the great medical triumph of the ninteenth century; discovered after years of untiring effort and research by the eminent kidney and bladder specialist, Dr. Kilmer, and has truly wonderful healing action on the kidneys and bladder.

It will be found by both men and women just what is needed in all cases of kidney and bladder disorders, lame back, dull pain or ache in the back, gravel, catarrh of the bladder, rheumatism, sciatica, neuralgia, uric acid troubles and Bright's Disease, which is the worst form of neglected kidney trouble.

Swamp-Root corrects inability to hold water and promptly overcomes that unpleasant necessity of being compelled to go often during the day and to get up many times during the night.

If your water when allowed to remain undisturbed for twenty-four hurs forms a sediment or settling, or has a cloudy appearance, it is evidence that your kidneys and bladder need immediate attention.

The way to be well is to look after your kidneys. To take Dr. Kilmer's Swamp-Root when you are suffering from clogged kidneys.

This prompt, mild and wonderful remedy is easy to get at the drug stores in fifty-cent and one-dollar bottles. Make a note of the name, SWAMP-ROOT, Dr. Kilmer's Swamp-Root, and remember it is prepared only by Dr. Kilmer & Co., Binghampton, N. Y.

Swamp-Root has been tested in so many ways, in hospital work, in private practice, among the helpless too poor to purchase relief, and has proved so successful that a special arrangement has been made by which all readers of the DAIRYMAN, who have not already tried it, may have a sample bottle sent absolutely free by mail. Also a book telling more about Swamp-Root and containing some of the thousands upon thousands of testimonial letters received from men and women who owe their good health, in fact, their very lives, to the wonderful curative properies of Swamp-Root. Be sure and mention HOARD'S DAIRYMAN when sending your address to Dr. Kilmer & Co., Binghampton, N. Y.

ARE YOU PROUD OF IT?

Are you proud of the butter you are making? Has it good grain? Has it the delicious June tint? Is its flavor all right? **Will it stand the Fuller's Earth test for analine dye?** Remember this test can be made in five minutes by any housekeeper, and also remember that if she finds analine dye there, her custom is gone from you forever.

Thatcher's Orange Butter Color

Will give every desired quality to butter that is otherwise all right.

IT PLEASES THE EYE, AS GOOD BUTTER DOES THE TASTE.

It is made from pure vegetable substances, and is healthful. Analine dye is found in many butter colors. It is a deadly poison and is prohibited by law. The Fuller's Earth test will discover it every time. For a Sample bottle of Thatcher's Orange Butter Color, write

Chillicothe Ohio
Gentlemen —
On the afternoon of the 9th inst - the Low Down Milk wagon shipped by you to this place on the first came to hand without a mark or scratch on it. "It is a Dandy" my boys would not take $1000 for it. On Sunday morning they hitched up a span of match Texas Ponies yellow with white Mane and tails with a nice set of Harness and taken in the town every one wanted to know where that wagon came from.
I am well pleased so far and should me or my boys need anything in that line in future we will not forget you
Yours Truly Wm A Fletcher

We have a Dairy with 110 Head of Registered Stock right at our door, and in handling the distribution of this immense product, nothing but the most practical time and labor saving devices are used.

E. B. O. SMITH,

National Wagon Co
Chillicothe O
Gentlemen
I have intended writing for some time to tell you how I liked my wagon.
It came all right on time and since put on the streets has been the talk of the town the universal verdict is that it is the "smallest business turnout ever put on the streets of the town."
If ever a wagon got a critical examination mine did the other day by the representative of another factory. (one I had corresponded with before buying) and all he could say was this was shorter coupled and for that reason lighter draft" he said more was worth the money and finally requested that I drive out where he could take a photo of it.
If I can do you any good refer to me
Respectfully Yours
E B O Smith

"The New Dairy Wagon,"

Produced by our own Artists from life.

THE NATIONAL WAGON COMPANY, Chillicothe, Ohio.

THE LARGEST AND MOST COMPLETE DAIRY WAGON SHOPS IN THE WORLD.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade, aggregated 9,840 pounds. All bids were at 19 cents, and all sales at this figure. The Quotation Committee announced the market steady at 18½ cents.

The sales reported were as follows:

Factory.	*Pounds.*	*Price.*
Red Clover	1,200	19c.
McConnell	1 0?0	"
East Burlington	900	"
Shabbona	1,080	"
Shabbona Grove	840	"
Shattock's Grove	2,400	"
Malta	1,500	"
Keystone	840	"
Total	9,?40	

The sales for the corresponding week of the three preceding years were as follows:

April 18, 1898, 16,500 lbs. of butter sold at 17c.
April 19, 1897, 40,680 lbs. of butter sold at 16@16½c.
April 20, 1896, 81,120 lbs. of butter sold at 14@15c.

The New York butter market Monday was reported steady at 19 cents. H. C. B.

Elgin, Ill., April 17, 1899.

CONCERNING OUR ADVERTISERS.

GET YOUR MONEY'S WORTH.

The American farmer knows where to get his money's worth. That is why he buys the McCormick in vast majority. The great record of 189,760 machines built and sold in 1898, was made by the McGormick Harvesting Machine Company of Chicago. These figures utterly transcend those of any other agricultural implement factory on earth. There is a reason for this; it arises from the masterly construction of the McCormick machines. They are the most modern of all machines upon the farm. Each machine turned out of their gigantic works possesses a genius in design, an accuracy in workmanship and strength of material which surpasses all rivalry. The agriculturalist who wants to be a happy farmer, is attracted to the McCormick machines. He has the absolute certainty of his money's worth when he buys "The Best in the World."

WORTH TRYING.

A farmer recently wrote his name and postoffice address on a postal card and addressed it simply to "Deering, Chicago." By return mail he received from the Deering Harvester Company a catalogue with over 100 fine half-tone illustrations, containing a picture of the largest factory in America, a "twine booklet" on the subject of binder twine, a copy of the Deering Farm Journal, and a personal letter—All for a postal card. Try it.

The advantages of a cash buying principle are much more highly appreciated than formerly. Present indications point to the fact that at no very distant date the long drawn out interest bearing account will be a thing of the past. Cash buying is a business short cut, it is the little path that leads across the fields It saves business distance.

Cash selling and buying has gradually led up to another method of conducting business, which is to sell direct from the manufactory to the consumer.

Take for instance the Elkhart Carriage and Harness M'f'g. Co., of Elkhart, Indiana They sell everything they make direct from the factory to the consumer. Their terms are either cash with order or C O. D. with fullest privileges of examination, and their experience is that the cash buying principle is growing upon the people. By far the greatest percentage of their orders contain cash remittance. This is very complimentary to the Elkhart people and their fair business methods. They are undoubtedly the largest manufacturers of vehicles and harness in the world selling direct to the consumer.

VETERINARY.

Queries in this department answered by WM HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

CALF SCOURS.

I have lost two calves lately. They came all right, and in two or three days seem to have a very bad diarrhoea. They seem to be in pain and nothing comes from them but water, and they soon quit sucking and they die in a couple of days. Can you tell me what to do or what is the cause?

ANSWER.

There are so many cases of scours in calves now-a-days, that it points seriously to one great common cause. Whatever the cause, the general treatment is the same. Slippery elm, flax seed tea, island moss, oil cake porridge, gum arabic, oat meal gruel, etc. To each pint put a piece of unslacked lime as large as a hickory nut. The gruels can be changed so as to get the best suitable.

CALF SCOURS—TREATMENT OF BAG.

I have lost three calves and all the rest, eight more, are sick same way, but I gave them paragoric and saved their lives. They are born all right, lively and hearty, but in two or three days were taken with dysintery and their bowels run like water and became badly swollen. I fed the cows on hominy chop and bran, one-half and one-half, and dry corn fodder and clover hay.

2. Also what is best remedy to rub a bag with. When calf was born, the bag was hard and took a few days to get it soft. I used to rub with hog's lard and gum camphor dissolved or melted.

3. I also have a cow that, when she had her first calf, had a perfect bag but second calf was neglected by her owner and her bag got hard on one spot and only a small amount of milk comes out of that teat, but that comes free. Is there anything I can do to soften that place and get a full flow of milk from that teat? This it her second calf since it happened. W. S. R.

Md.

ANSWER.

Give slippery elm tea, flax seed tea, island moss, gum arabic, oat meal porridge—any of them, one at a time—about a pint or less, gradually. Put into each pint, fluid extract of ginger, two teaspoonfuls; don't give any rough sort of food for a while, keep the stools constantly washed off thoroughly. Keep well calves away.

2. Hand rubbing, thoroughly, and fish oil.

3. Same as No. 2 and a dilating plug.

GROWTH IN NAVEL.

Large cow has a large protuberance about navel, say 8 inches long and 2 inches thick in center. It is growing harder. What is proper treatment? I am applying external irritant. J. W.

Rapidan, Va.

ANSWER.

Paint over with strong tincture of iodine several times daily. Internally give 80 grains of iodide of potassa for 10 or 20 days. Give also a full dose of physic, and repeat; repeat if needed 5 to 7 days apart.

ABORTION.

I have a full blooded Jersey cow that has aborted three times out of four. Calves come too soon to bring a flow of milk; head of calf about the size of that of a goose. This cow has been a dead loss to me for several years, but because she is a thoroughbred, and a very handsome cow, one that I bought as a heifer from a Jersey cattle raiser to aid in building up a Jersey herd, I am loath to part with her to the butcher.

Lynchburg, Va. J. C.

ANSWER.

I refer all such cases to the special medicines advertised in the DAIRYMAN. It is fully as cheap as medicines I have been recommending for some time for the prevention of abortions, this had to be compounded by inexperts. The medicines had in many cases to be gotten at country drug stores, etc., and was quite often of no value, from being old shop stuff; then again, it was quite often inaccurately compounded.

A LAME LEG.

Have a cow that was taken lame in right hind leg about two weeks ago and there seems to be no improvement. There appears to be a bunch on the outside of the leg just below the stifle. L. L. S.

Ft. Atkinson, Wis.

ANSWER.

Cut off the hair close then paint over with the Gombault's Caustic Balsam several times a day. When you have raised a good blister cover with clean lard, daily, until the scab comes off easily. Then, if needed, repeat and so on.

SUDDEN BLINDNESS.

I have a two-year old Jersey heifer that has become blind. When I turned her out in the morning she was all right and when I put her in she was blind. She is in good health and her eyes look natural.

Naomi, Mich. SUBSCRIBER.

ANSWER.

Your case is beyond all correspondence. Paralysis of the optic nerve is quite a serious condition. Get a genuine veterinarian or your family doctor to examine the eye and act accordingly.

ABORTION.

I have read with interest your reply to R A.W. in the DAIRYMAN of recent date respecting the "hypodermic treatment for abortion."

I have about fifty cows and am losing more than half of my calves. They are born at from five to seven months. Heifers are the worst to abort.

Cows are well fed on sorghum hay, corn fodder, all they will eat, and about 8 lbs. bran, 2 lbs. cotton seed meal, and 3 lbs. corn and cob meal per day. E. T.

Edwardsville, Kan.

ANSWER.

Select one of the special remedies advertised in the DAIRYMAN. Cotton and cob meal is one of the worst foods known for breeding cows. Cotton, in all its forms, is a positive abortient.

LUMP ON JAW.

We have a cow with a lump on her jaw, which runs perpendicular with jaw where it joins neck, that is, from ear downward. It started about five weeks ago, and has been getting larger, gradually, until now covers whole back of jaw, and sticks away out.

Meramec Highlands, Mo. B. C. B.

ANSWER.

All such and similar cases need a good expert to make a professional examination, and act accordingly. All these sort of swellings are very suspicious of serious conditions. No approximate diagnosis can be made by correspondence.

CHEMICAL DEHORNING.—PIG SCOURS.—BREEDING FROM TWINS.—ABORTION.

1. Is caustic potash in liquid or solid (paste form) used for dehorning calves? At what age, how to apply, and how many times? Is four to five weeks too old?

2. How to treat scours in pigs?

3. Are catttle liable to take infection from hog mange or itch?

4. If the male or female is one of twins, which one would have the greater power to transmit these tendencies?

5. If abortion exists in the herd, and they were not sired by the "head," is he liable to infection?

Cedarburg, Wis. M. H. M.

ANSWER.

1. Some persons use caustic potash for dehorning calves, or rather, preventing the growth of the horns.

2. Keep clean; change the food gradually; plenty of pure air and sunlight, charcoal, hard coal screenings, and a little clean chalk once a day, for two or three days. Grass as soon as practicable.

3. Yes.

4. All depends upon the prepotency.

5. Don't understand your meaning by the head. Bulls do get infected quite often.

LAMENESS IN LEG.

About four weeks ago I went to woods and put on a load of logs; my mare got stiff; brought her to barn. She laid down for three days, then got up. Is lame in right hind leg; seems to be lame in hip. Please give a remedy. J. B.

Sheboygan, Wis.

ANSWER.

No doubt your mare was strained across the loins. Log hauling is responsible for many similar cases. Strong oak decoction tea, two quarts; acetic acid, half a pint. Bathe over loins, and the lame leg six to ten times a day. Don't attempt to work her. Give her a good soft hay bed.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.* Every bottle sold is warranted to give satisfaction Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars.

FITS Permantly Cured. No fits or nervousness after first day's use of Dr. Kline's Great Nerve Restorer. Send for FREE $2 trial bottle and treatise Dr. R. H. KLINE, Ltd., 931 Arch St., Philadelphia, Pa

CANCER cured at home. Send four cents, stamps. 80 page book illustrated Dr. J. B. HARRIS 2226 Kemper Lane, Walnut Hills Cincinnati, O.

The work of a farmer's wife is never ended. But it is wholesome, enjoyable, productive work that is pleasurable if the farmer's wife is a well woman.

The work becomes weary drudgery when the woman is sick. The work drags and the woman's pride is hurt. Her ambition is to do as much and better work than her neighbors. It is a distinct triumph if her butter is generally regarded as the finest in the county. But fine butter and bad health don't go together.

Mrs. W. J. Kidder, of Hill Dale Farm, Enosburg, Vt., writes to Dr. R. V. Pierce, Buffalo, N. Y.: "During the past year I found that I was to become a mother and that I was in rapidly failing health. I suffered dreadfully from bloating, and urinary difficulty. I was growing perceptibly weaker each day and suffered much sharp pain at times. I had to give up my work and I felt that something must be done. I sought your advice and received a prompt reply. I followed your directions and took twelve bottles of Dr. Pierce's Favorite Prescription, and also followed your hygenic instructions. I began to improve immediately, my health became excellent, and I could do all my work (we live on a good sized farm). I walked and rode all I could, and enjoyed it. I had a short, easy confinement and have a healthy baby boy."

The one medicine that gives prompt and sure relief is Dr. Pierce's Favorite Prescription. It is a tonic and purifier that works on one special set of organs and puts them in a perfectly vigorous, healthy condition. It quickly soothes inflammation and stops debilitating drains on the system. Taken regularly during the period of gestation it greatly lessens the pain and danger of childbirth.

Although sweet to the taste it contains no sugar which often disagrees with weak stomachs; nor does it contain any alcohol, or opium in any form, and therefore does not induce a craving for stimulants. Keeps perfectly in any climate.

ROBERTS' ANTI-ABORTION SERUM

Hypodermatically administered, is a **POSITIVE CURE** for abortion in cows. SWORN testimonials furnished on application. **Dr. D. ROBERTS,** Veterinary Surgeon, Address, **Waukesha, Wis.**

ABORTION!

Retention of Placenta and Failure to Breed.

H. W. KELLOGG'S experience with and positive cure for these diseases in cows. Send for circulars. Address all communications to **H. W. KELLOGG COMPANY, Ripon, Wis**

ANTIABORSIO.

WILL PREVENT ABORTION in cows and cure scours in calves. One galion will treat twenty cows three months.

Our Specific No. 1: Absolutely prevents Hog Cholera and Swine Plague, and will cure 90 per cent. of sick hogs

Our Specific No. 2: Prevents and cures Roup and Gapes, and kills Vermin on Poultry, also kills **Ticks on Sheep.** Theseare established facts, not experiments.

Our remedies are liquid germicides applied by sprinkling in closed stables and pens. Cures by inhaling fumes which destroy the germs of disease.

Send for free booklet and testimonials.

Animal Germicide Co., 319 Washington St., N. Y.

Dr. Horne's Anti-Abortient

Prevents Abortion and cures Nymphomania—failure to breed; also Emmenagogue Powders for cows failing to come in heat. Both powders are the result of long practical experience and study and may be given in a little moist feed. 5 oz. $1, 11 oz, $2, 23 oz. $4, 50 oz. $8, by mail.

Also Specific for SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM. HORNE, Janesville, Wis.

Mr. EUCLID N. COBB, of Monmouth, Ill., better known to our readers as "Buff Jersey," has published a small pamphlet entitled "The Dairyman's Hand Book," which is replete with sound advice and timely admonition, gathered in an experience covering many years of active association with cows. He has induced several enterprising business men to give him advertising enough to cover cost of publication and will therefore send a copy to anyone who will forward a two cent stamp to cover expense of postage and wrapping.

Experience with Abortion and Calf Scours.

ED. HOARD'S DAIRYMAN:—As there always seems to be some one in trouble by having abortion in their herds, I thought I would give my experience for the benefit of W. J. A. and others.

I keep about forty cows and two years ago they commenced aborting and about every other one would abort. They continued through the year '97 and commenced again in '98, two or three of them performing the act the second time. I commenced feeding them carbolic acid in the following manner:

Two ounces carbolic acid in one gallon bran, thoroughly hand rubbed in the bran, then mix this with two gallons coarse salt and keep this where the cows can get at it every day.

Do not feed any other salt while feeding this; also with fine spray, (five gallons water and one pint carbolic acid), disinfect all posts and prominent doorways, stalls, and mangers on premises, also the affected cows. I never lost one case after using this method.

We have lots of scouring calves in this valley, and we find that a little spice tea, made from any of the spices that our good wife always keeps on hand, will check it better and quicker than anything else we have tried. W. S. M.

Randolph, Utah.

Vetch Experience Wanted.

Also Experience Growing Protein in Corn Belt.

ED. HOARD'S DAIRYMAN:—Can you or any of your readers give experience with vetch, sent out so lavishly by the government last spring? I sowed alone in drills, and broad cast; also broad cast with oats, but got nothing over six inches in height.

Also, has there been any experiment recorded in which the attempt was made and proved that the protein supply for a dairy farm in the corn belt can be grown successfully, financially?

I have tried this to some extent, but am not at all convinced of it on 50 bushel corn land or better, and experimenting while trying to live, is very wearing, both on nerves and pocket. J. P. D.

Fowler, Ind.

J. P. D. has raised some important and vital questions. The United States is at considerable expense every year, in the distribution of seeds of various kinds. Much of this expense is worse than useless, and the Department of Agriculture has repeatedly urged Congress to repeal the law making such distribution compulsory, but for reasons which it is unnecessary to specify in detail, congressmen have not been willing to surrender this to them cheap method of complimenting their constituents. It is, of course, perfectly legitimate and proper for the general government to secure and distribute sample packets of new and untried varieties of grains, vegetables and forage plants, in order to ascertain their adaptibility to various soils and climates, and that is the theory upon which the vetch seed was distributed last year. Our Indiana friend and all others who received seed should report to the Secretary of Agriculture, the results obtained, and in due time these reports will be published.

Meantime, if there are other readers of the DAIRYMAN who tried vetches last year, we should be glad to hear from them.

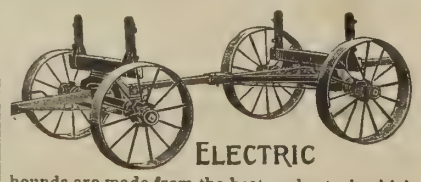
As will be seen, in reply to an inquiry from Pennsylvania, our opinion is that it is not practicable to raise all the protein feed on the farm, but that is no reason why one should raise only corn. It is indispensible if one expects to maintain the fertility of his soil and continue to produce crops at a profit, that he pursue some system of rotation. All corn, all cotton, or all wheat, year after year, will bankrupt any soil or any farmer. The dairy farmer in the corn belt, above all others, should include clover or other leguminous crops in this rotation, not alone for the conservation and improvement of the fertility of the soil, but for the added reason that such crops supply him in part with the much needed and expensive protein, without which it is impossible to produce milk. In the alfalfa "belt," where the protein is over abundant, he should raise kafir corn, sorghum, or some variety of common corn (maize).

Peas and Pea Hay.

ED. HOARD'S DAIRYMAN:—On page 151, A. D., of Marion, Ind., asks about pea hay. We have raised from 5 to 30 acres peas and oats every year for the past five years. Sometimes making hay, and sometimes ripening and threshing for grain crop.

If we have a heavy piece of sod filled with wire grass or June grass, or badly infested with Canada thistles, of which most farmers in this section have an abundance, we use it for our pea crop. Soil here is heavy clay loam. Plow just after corn is planted, good depth, work the ground with disk and spring-tooth, rolling several times while fitting, until it is well mellowed, when we set our drill so it will run at least four inches deep.

We sow 2 to 2½ bushels per acre of the small Canada peas, broad cast, about 1½ bushel oats per acre just ahead of drill. The reason we sow about June 1st to 10th is, we get a heavier crop. It chokes out thistles more completely and will entirely rid the land of wire or June grass, so hard to get out of the land here.



It leaves the land more loose, and it fits it for wheat nearly as easily as a summer fallow, rotting the sod out more completely than can be done with a summer fallow. Our mode of harvesting for hay is the same as we would handle a crop of clover, cutting when lower pods are about right to cook, and oats will be nearly all headed. We keep an old set of knives to use on mower for this business, as it is hard on them, for we like to cut as close to the ground as possible, so ground will be clear to fit for wheat.

If we wish to save a portion for grain crop, we use mower just the same; only we take three men with us to pitch the swath out of the way, so horses and machine will not run over them. In starting have one man follow up and roll swath ahead until he gets a good sized forkful, then roll it to one side, and so on; second man going half way round the piece, and starting in as the first one did; the third remaining at the starting point to take up second swath. In this way each man will take up an equal amount, and by the time machine is half way around on second swath, the first man will be there ready to start in after you. In this way four men and team will cut and leave in windrows ten acres a day. E. L. M.

Armada, Mich.

BUY THE BEST.

If you want the best low down wagon you should buy the Electric Handy Wagon. It is the best because it is made of the best material; the best broad tired Electric Wheels; best seasoned white hickory axles; all other wood parts of the best seasoned whiteoak. The front and rear

ELECTRIC

hounds are made from the best angle steel, which is neater, stronger and in every way better than wood. Well painted in red and varnished. Extra length of reach and extra long standards supplied without additional cost when requested. This wagon is guaranteed to carry 4000 lbs. anywhere. Write the Electric Wheel Co., Box 130 Quincy, Illinois., for their new catalogue which fully describes this wagon, their famous Electric Wheels and Electric Feed Cookers.

EXPANSION

Last season the McCormick Harvesting Machine Company of Chicago built and sold 189,760 machines. This kind of expansion dwarfs every other achievement American history records in favor of the well being of the farmers. Buy McCormick machines and you will get your money's worth.

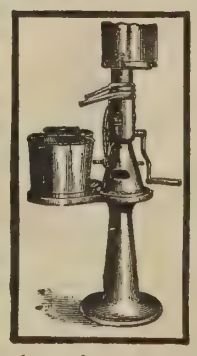
THE CUTTING KIND

The **Deering Ideal Mower** is the best modern representation of a grass cutting machine that will cut.

The light draft of the **Deering Ideal Mower** is due to the fact that the Deering roller bearings have practically annihilated friction.

The **Deering Ideal Mower** runs almost noiselessly and has no lost motion.

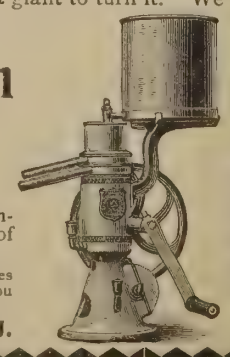
The **Deering Ideal Mower** is quick acting and positive. Every ounce of horse power is saved. The knife starts with the wheels. No backing up to "get a start."



The **Deering Ideal Mower** has an adjustable cutter bar that is always in line; the hand levers and foot lift are handy and quick-acting.

The unsatisfactory mowers cost less money than the Deering Ideal, but the **Deering Ideals** are the *cutting kind.*

Send for the descriptive booklet, "Light Draft Ideals."

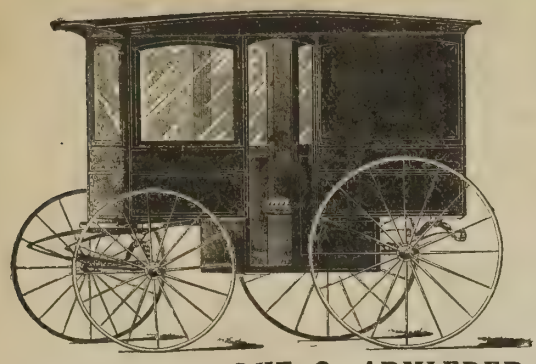


DEERING HARVESTER CO.,
CHICAGO.

A Hand Separator

to be profitable must not only extract every particle of butter-fat from the milk, but must run so easily that it does not require the strength of a giant to turn it. We guarantee the

Empire Cream Separators



to run 50 per cent. easier than others of equal capacity. Their record for clean skimming is unequalled. We have the most complete line of hand separators in America; also power machines.

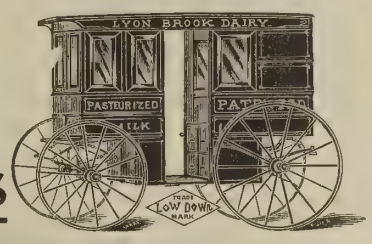
We have not space here to tell you why the **Empire** machines excel all others, but it's all in our catalogue. Send your address if you have one cow or one thousand.

U. S. BUTTER EXTRACTOR CO., Newark, N. J.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.



Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

There Are Others

But they all came after ours.

WE ARE THE ORIGINATORS

Of the now famous "LOW-DOWN" Milk Wagon.

Imitation is an acknowledgement of real merit. Thirteen years' trial has proven the Parsons "Low-Down" Wagons to be **THE BEST.** Secure our catalogue of strictly first-class, hand made, up-to-date, durable work.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY.
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premum.

or

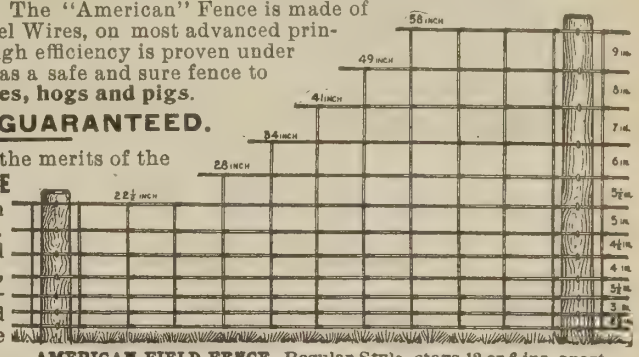
Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehenisve from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.



THE FENCE THAT FENCES.

"AMERICAN" ALL STEEL WOVEN WIRE FIELD FENCE.

Large, strong wires heavily galvanized. **Tension curve** at every intersection of main strands and stay wires, provides for expansion and contraction. 17 Penn. Av., Pittsburg, Pa.

ACME PULVERIZING HARROW, CLOD CRUSHER AND LEVELER

For all soils, all work—crushes, cuts, lifts, pulverizes, turns and levels. *Cast steel* and wrought iron—therefore *indestructible.* Cheapest *riding* harrow and best pulverizer on earth. Sizes 3 to 13½ feet. Catalogue free.

SENT ON TRIAL to be returned at my expense if not Entirely Satisfactory.

I deliver free on board at New York, Chicago, Columbus, O., Louisville, Ky., Minneapolis, San Francisco and other points.

Address DUANE H. NASH, Sole Mfr., MILLINGTON, N. J., or CHICAGO, ILL.

PLEASE MENTION THIS PAPER.

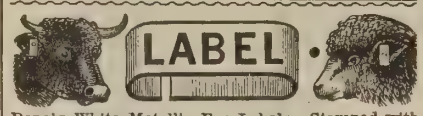
THE FAMOUS KEYSTONE LINE OF SEEDING, PLANTING AND CULTIVATING TOOLS.

Victor Disc Harrow —greatly improved for '99. Oil tubes to the bearings from top of frame—positively exclude all dust or dirt. Steel scrapers, double adjustment levers—easy to place gangs at any angle. Ball bearing—no side pressure and easy draft. Made 4, 5, 6, 7 and 8 ft. wide, with 18 or 20 in. discs. SEEDER ATTACHMENTS are made for 6, 7 and 8 ft. disc harrows.

Keystone Force Feed Broadcast Seeder are made 8½ or 11 ft. wide. Sows broadcast all small grains in any quantity in the best possible manner. Mounted on low steel wheels. Made with or without grass seed attachment. Equipped with CULTIVATOR ATTACHMENT if ordered. Made with end wheels or middle wheels. Has the best force feed we know. Send for special Seed Circulars.

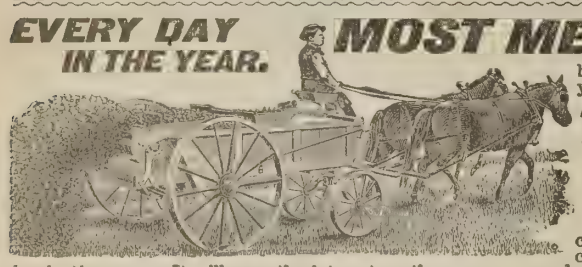
Keystone Rotary Drop Corn Planter —it's a whole hill drop, each hole in seed plate holds enough grain for a hill. It never skips or misses. Equipped with Automatic Wire Reel. Has a drill attachment. Gear throws out automatically at end of row. Always drops at even depth because of the shoe gage on each runner.

Keystone Potato Planter —sprung quickly into popular favor because it is a simple and effective machine for the purpose at a reasonable price. Fits the needs of the man who grows an acre or two of potatoes, but who is not regularly in the business. Plants 10, 14, 17 or 20 inches apart in rows. Send for circulars.



Keystone Walking Cultivator. This is clearly a leader among the machines of its class. It is made entirely of steel and iron except tongue, singletrees and neck yoke. Strong and well braced in every way. Steel braces and four soft centre steel shovels. Full line of Riding Cultivators also. Send for circulars.

KEYSTONE MANUFACTURING CO., 39 RIVER STREET, STERLING, ILLINOIS.



Newton's Improved **COW TIE** Holds them firmly, draws them forward when lying down, pushes back when standing, gives freedom of head, keeps them clean. E. C. NEWTON CO. Batavia, Ill. Catalogue Free.

This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY AT ONCE.

FITCH CHEMICAL COMPANY, Bay City, Michigan.

A Square Talk.

For some years the dairy farmers and creamerymen have felt the pinch of hard times to such an extent that they have been buying the lowest priced articles the market afforded, and they have had to renew them every year. Our great factory and immense output enable us to put on the market a line of dairy supplies of the highest quality at first cost prices, no higher than the poorer ones, and with good lasting qualities.

DAIRY SUPPLIES. . .

Our Vats and Churns are unsurpassed. We carry in stock the well known SHARPLES CREAM SEPARATORS, which can be run profitably with a dairy of only five cows. The No-Tin 6-Bottle Babcock Test that will do accurate work and last a life time.

WHEN BUYING AN OUTFIT

It will pay the intending purchaser to specify that it shall be of the Haney-Campbell make. Order from your nearest dealer if you prefer, and he will send to us for it. ☞ Catalogue on request.

IN THE FACTORY.

The U. S. Takes the Cake.

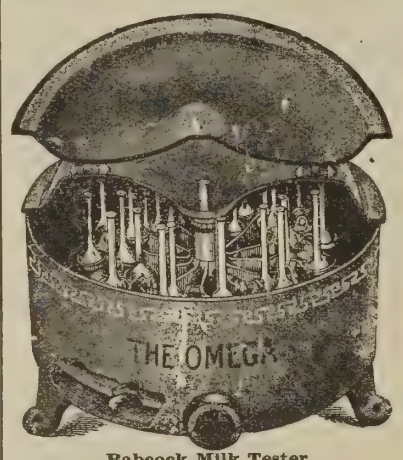
POYNETTE, WIS., Jan. 20th, 1899.

Have been running U. S. Separators since 1892, and can cheerfully say that the new No. 1 Improved U. S. Separator takes the cake. When the skim milk is tested it shows only a trace of fat. I won the sweepstakes and three other first prizes, amounting in value altogether to $115.00, at the 1898 Wisconsin State Dairymen's Association, and all because my No. 1 U. S. Separator makes such smooth, perfect cream.

R. M. BUSSARD, Prop. Bussard's Creamery.

AND IN THE DAIRY.

Very Durable, Very Easy to Operate, Never Out of Order.



TIFFIN, OHIO, Nov. 28th, 1898.

Have used the No. 5 Improved U. S. Separator nearly three years and do not think it is worn a particle. It runs as smooth as the day we first started it. **It is the best separator in the world,** it is so easily run and so easy to clean, and it is always in order to do the best of work. We wonder how we ever got along without one. We think very much of the enclosed gearing. You have the best machine I know of in running and mechanical construction.

Good Advice for All of Us.

Plant flowers in the soul's front yard,
Set out new shade and blossom trees,
An' let the soul once froze an' hard,
Sprout crocuses of new idees.
Yes, clean yer house, and clean yer shed
An' clean yer barn in ev'ry part;
But brush the cobwebs from yer head
An' sweep the snow banks from yer heart.
—*Sam Walter Foss.*

COLD water, cold barns and cold air have to be heated with butter fat, if the cow is to keep herself warm. There are lots of dairymen, who have not found it out yet—but their pocket-books have.

MILKING SCRUB COWS.

We have the privilege of placing before our readers this week, the record of a herd of scrub cows for the year 1898 at the Kansas Experiment Station, Manhattan, and in connection therewith, illustrations of one cow yielding 383.7 pounds butter fat, and of another, receiving similar feed and care, yielding only 135.7 pounds, or a trifle more than one-third as much. The photographs from which these illustrations were made, were taken about four months after the cows were received at the station. This would be about April 1st, and before they were turned to grass, and after they had been milking for four months.

This experiment is exactly in line with the one at the Michigan Station, reported a few weeks since, with the exception that there is a much wider difference between the best and the poorest cows. Both experiments confirm what the DAIRYMAN has so often tried to impress upon the minds of its readers, to the effect that good care, and proper feeding will pay; that there is great virtue and true economy in balanced rations. It would seem as though the results reported from these stations, ought to go a great ways in disabusing the minds of many dairymen in regard to "book farming," and the application of the teachings of science to the every day affairs on the farm, and with the dairy.

If it should be claimed that the average of $16.25 per cow, over and above the cost of feed, with this Kansas herd, is not a very bad showing, we answer that it is very much less than it would have been had the best six cows only been brought into the calculation; and if we include only the best three cows, the discrepancy is still greater. Our contention is that it is not only possible, but comparatively easy to have a herd that shall average as well as the best three, and that any dairyman is losing money that does not have such a herd. When a net income of $30 per cow is possible, what sort of business judgment does a man exercise, who spends his time with a herd that averages only one half as much? Or in the language of Prof. Otis in the bulletin, "Is stronger argument needed to induce Kansas dairymen to cull their herds, and keep only the best?"

Comment on the illustrations seems to be unnecessary. Number 20, if not of the extreme dairy type, approximates it, and number 5 is about as far removed from it as possible.

We also call attention to the manner in which these cows were fed. It will be remembered, that time and again HOARD'S DAIRYMAN has said that alfalfa hay and corn, practically supplement each other, and will furnish a balanced ration. In Kansas they substituted kafir corn for the common field corn (maize.) It may be noticed further, that when these cows were in pasture, three-fourths of the grain allowance was corn meal, and the remaining fourth bran,—the latter used, probably, more for distending or diluting the corn, than for its specific nutritive effect.

Following is the bulletin in full:

From January 1 to April 15, 1898, the College bought thirty head of common scrub cows, with the object of testing the value for the dairy of this class of cows when properly handled. These cows were purchased in Lincoln county, cost delivered at Manhattan an average of $34 each; were selected by a farmer who was not a dairyman, and in quality were below the average cows of the state. The cows were shipped from Lincoln county to Manhattan (100 miles) in mid-winter, the excitement and weather causing a serious drop in the milk yield of those that had calved. The first week the average daily milk yield per cow was fifteen and one-half pounds, the second week twenty-one pounds.

SCRUB COW NO. 20, KANSAS EXPERIMENT STATION.

Record for 12 months, 9,116 lbs. milk, containing 383 7 lbs. butter fat. Food cost of butter fat 8.5 cents per pound.

At the start, the cows were fed alfalfa hay and a mixture of two-thirds bran and one-third old process linseed meal, a ration rich in protein, designed to stimulate the milk flow and to partially overcome the effects from shipping. As soon as the cows were brought to a fair milk flow, they were put on a ration of alfalfa hay and kafir corn grain. This ration produced the greatest flow of milk with butter fat at least cost, but had to be dropped at the end of seven weeks, so that various feed stuffs could be fed in order to show our dairy classes the effect of various feeds on the texture of butter. The daily grain ration averaged about eight pounds per cow while on dry feed. While on pasture, the daily grain ration averaged three pounds of a mixture of four parts corn meal and one part of bran. Alfalfa hay was also kept in a rack where the cows could eat it at will, when they were brought in at milking time. The yield held up well through the fall drouth. For a short time green kafir corn was fed with the pasture, and the cows were pastured on wheat in the fall until the ground became frozen.

Twelve cows were fresh when received January 5, the rest calving in from one to five months. The records here given are for the twelve, for 1898. The butter fat yielded has been credited at the prices paid each month by the Manhattan creamery, which were as follows: January, 17½ cents; February, 17 cents; March, 16½ cents; April, 15 cents, May 14½ cents; June 13 cents; July, 13½ cents; August, 15½ cents; September, 16 cents; October 18 cents; November, 18 cents; and December, 17 cents

The feed has been charged at the average retail price in Manhattan for the year: Cost per 100 pounds—corn meal 55 cents, kafir corn meal 55 cents, linseed meal $1.25, soy bean meal $1, bran 55 cents, cotton seed meal $1; cost per ton, alfalfa hay $4, corn ensilage $1; pasture 75 cents per month. It would pay many Kansas farmers who live distant from market to milk cows, if through the milk they could obtain the above prices with no additional profits.

RESULTS.—Average yield of milk per cow, 5,707 pounds; best cow, 9,116 pounds; poorest cow, 3 583 pounds. Average yield of butter fat per cow, 238 pounds; best cow, 383.7 pounds, poorest cow, 135 7 pounds Average cost of feed per cow, $29.20; best cow, $32 80; poorest cow $26.75. Average value of butter fat per cow, $37.75; best cow, $60.88; poorest cow, $21.39. Average value per cow of skim milk at 15 cents per 100 pounds, $7.69; best cow, $12 29; poorest cow, $4.83. Average income per cow from butter fat and skim milk, $45 44; best cow, $73.17; poorest cow, $26 22. Average receipts per cow less cost of feed, $16 25; best cow, $40.37; poorest cow, receipts 43 cents less than cost of feed. Average cost of butter fat per pound, 12.2 cents; from best cow, 8.5 cents; from poorest cow, 19.7 cents. The average price received for butter fat for the year was 15.8 cents. To the receipts given above should be added the value of the calf at birth.

SCRUB COW NO. 5, KANSAS EXPERIMENT STATION.

Record for 12 months, 3,583 lbs. milk, containing 135.7 lbs. butter fat. Food cost of butter fat 19.7 cents per pound.

This test shows the difference in value between different cows with feed and care alike. The year's record of our best scrub cow (9,116 pounds of milk; 383.7 pounds butter fat, equal to 451 pounds butter; value of products, $73.17; returns, less feed, $40 37) is one that many a pedigree dairy cow would be proud of. This cow is of mongrel breeding, but has a pronounced dairy farm. The poorest cow's form is a good beef type, and her yield of 3,583 pounds of milk and 135 7 pounds butter fat was worth 43 cents less than the feed she ate. Is stronger argument needed to induce Kansas dairymen to cull their herds and keep only the best?

This test shows that Kansas cows can be made to give greatly increased yields with proper feed and care. We collected the records of eighty-two herds owned by creamery patrons in one of the leading dairy sections of the state, finding an average annual yield per cow of milk 3,441 pounds, butter fat 104.5 pounds, value of butter fat $19.79 Contrast this with the average for the college scrub herd, milk 5,707 pounds, butter fat 238 pounds, value of butter fat $37.75; and remember that the college herd is much inferior to the average herd of the state.

We attribute the greater yield secured from the college scrub herd to three causes. First, at all times their rations were either balanced or contained an excess of protein—the material which builds blood and milk—while the Kansas cow, usually, when on dry feed, has only half enough protein. Second, kindness and shelter. Our scrub cows were petted, comfortably sheltered, never driven faster that a slow walk, and never spoken to in an unkind tone. Third, a full milk yield was secured through the summer drouth by giving extra feed.

ALL PRESERVATIVES DESTRUCTIVE TO DIGESTION.

At a trial of certain dealers in meats in Pittsburg, Pa., who were charged with using preservatives, Prof. F. T. Ashmon, chemist, testified that all preservatives were dangerous, and at best, were destructive to digestion. One of the most serious charges we have heard against "renovated" butter is that preservatives were used in the manipulation of the same.

But the point made by Prof. Ashmon should be borne in mind. Any preservative, if effective, must inevitably affect the natural fermentation which goes on in digestion, *and to that extent* injure digestion. It is here that its use is found so injurious in milk when fed to infants and small children. It would seem that no man could be found, so lost to all sense of honor, or humanity as to put anything in his milk that would injure a child.

THE ANTI-COLOR LAW SOLIDLY ENTRENCHED.

The people of this country are waking up to the merits of this oleomargarine business.

In Michigan and Illinois, as is well known, the dairymen and farmers of the state two years ago carried through the Massachusetts anti-color law, in spite of all the money and political influence the oleo manufacturers could muster. The Michigan law was declared void by the Supreme Court of that state because of the lack of an enacting clause.

The present legislature has re-enacted the law in spite of determined opposition, and great care has been taken that all legal requirements are fulfilled. We congratulate Dairy and Food Commissioner Grosvenor of that state, on the consummation which he has so devoutly wished for.

In Illinois, the stock yard magnates have made a bitter fight to have the law repealed. They have defeated its execution very largely but the legislature with the fear of a "wrath to come" have not yielded to the oleo demands and the law still stands. What Illinois so much needs is a Dairy Commission.

There is no use to have laws if their execution is to be thwarted, and it now looks as if the office of Dairy and Food Commissioner will be created in that state. The only state where the cause of honest butter has received a set back is in Kanaas. There were too many dirty politicians in the pay of the oleo gang in that legislature, many of them being farmers.

The farmers of Kansas have not yet been aroused to an understanding of the merits of this question. Many of them are fairly paralyzed over the remark of some cunning demagogue that "this is class legislation". Well, if putting down fraud, adulteration, and counterfeiting in food, is class legislation, let us have more of it. Such laws do classify, it is true, fraud and counterfeiting. They force men who would defend the swindle to go into their own class, and be counted. "Hence these tears."

There is a significant question to be asked in all this matter: Why do these legislators stand up to the rack and defend the law? Some of them are enemies to it in private and so declare.

It is because the farmers both Republican and Democratic have fired the postal cards into their ranks. The farmers have talked plain talk. They have shown a true American independence of character and the slick politicans know they will "vote as they have shot."

That is the kind of a farmer to be. When a man lets his politics run away with his patriotism he is of but little good to himself, his neighbor or his country.

The National Dairy Union has not been idle in all these contests. It is working in the steadfast hope that the farmers of the country will rise up as one man and exert their influenee on their members of Congress in support of the Davidson bill to tax colored oleo 10 cents a pound.

KEEPING THE CANS CLEAN.

There is serious trouble in every creamery in the land, over certain of the patrons not keeping their milk cans clean. The difficulty is largely because the patron does not understand the necessity of a clean can. He has never made any special study of this point, and there is no reason why he should know all there is to be known on this subject. But in such a case, he ought to be willing to take some other man's word for it, who does know, and because he will not do this, is the cause of all the loss and trouble that ensues.

Farmers complain that their skim milk sours too quickly after leaving the creamery. If every patron would thoroughly clean and scald his cans with *boiling hot water*, before he puts his milk into them, to bring to the creamery, his milk and all the milk would be in much better condition to keep, to start with.

Then if he would do the same thing, and add to it, scouring the seams with a brush *after the skim milk is emptied from them*, the can would be in much better shape to receive the fresh milk at the next milking.

It is evident that a great many patrons and their wives do not really know what it means to clean a can so it can safely hold milk, and not taint it.

Experiments have shown that milk stored in sterilized cans will keep nearly twice as long, as when kept in cans washed in the ordinary way. To clean a can thoroughly, or free it from germs, C. B. Lane, of the New Jersey Experiment Station, states that it must first be scrubbed, then scalded out with boiling water, care being taken that it is boiling, or, better still, use live steam under pressure. No living organism can withstand steam, not even bacteria spores, although some of them will resist a temperature of 203° F. If dairy houses are supplied with a boiler, it can easily be managed to turn cans over a jet of steam having a pressure of 15 or 20 pounds. After steaming, cans should be kept bottom side up, as bacteria tend to go downward. There are patent "milk can washers" on the market, which run by power, but for the ordinary dairyman, hand brushes will be found just as effectual, and economical.

The ideal way to be sure of having clean milk, would be, for the patron to have two sets of cans, one for the fresh milk, and the other for taking home the skim milk. Then when he empties the fresh milk cans have them thoroughly cleaned and steamed at the creamery, and at the same time have the skim milk cans cleaned, and likewise steamed before being filled with skim milk.

The creamery always has the hot water and steam, and it could easily fix up a can cleaning place, in addition. This method would greatly help the creamery to get sweet, pure milk, and help the farmer to longer keep his skim milk sweet.

A WOMAN'S ADVICE.

We hope it will be a long time before the dairy business of the country will be evoluted out of the valuable touch and sympathy of the farmers' wives. Mrs. J. L. Reid, of Delavan, Ill., read the following excellent essay before the Tazewell Co., Ill., Farmers' Institute:

Milk, when in its natural state, or in the form of butter or cheese, is an article of diet so useful and wholesome that dairy management, which includes all that concerns its production and treatment, constitutes a most important branch of husbandry.

* * *

The first step of importance is to get a good milk cow. Make a study of cows if you have not already done so. Subscribe for dairy papers and study them. Then attend the fairs, visit the dairy barns and talk with the exhibitors about their cows, getting the experience of all; also talk with those who exhibit butter, notice the scorings, and if you find the judge at leisure talk with him, have him point out the difference between samples; it will be a great help if you are interested in the subject.

The cows must be well stabled; whatever the material used in constructing a barn, let there be plenty of light and sunshine. Have a southern exposure, if possible; keep it warm, clean and well ventilated.

Well cured clover hay, with mixed feed of corn and oats ground, and bran once in a while for a change, will produce a milk that will make a firm butter. It is very important that they should have plenty of pure water.

It is being strongly advocated to have the water warmed in winter. A recent writer asserts that five dollars, per cow, for the winter would be a low estimate of the value of warmed water over that of ice water.

The next thing required is a place to keep the milk. It ought to be a room adjoining the kitchen, or at least opening from the porch. Oh! the weary, weary steps one has to take for want of thought or management. It should be large enough to accommodate all the furniture one needs, churn, scales, chest, table, refrigerator, print, etc., also have it well lighted and ventilated. The water chest should be thoroughly cleaned once a week. Water standing a length of time becomes slimy and a bad odor arises, tainting the cream and butter.

While good butter has been, and can be made from using crocks or pans, if one is to handle a quantity of milk, it is much easier to use a creamery, or a separator, preferably the latter, as one gets a greater per cent of cream from the milk, and the work can all be done at once.

After milking each cow, the milk should be strained into a can and be covered, keeping the dust and odor from it. If the deep setting method is used, the milk should stand 24 hours in order to get the greatest quantity of cream. Late writers advocate 12 hours. Experience will teach one how long to let it remain before skimming. Skim into cans and keep sweet until having the desired quantity for churning.

In winter, place the can in a tub of hot water, stirring constantly until it reaches 80°, then pour in a cup of sour cream or buttermilk to facilitate ripening; let it remain in a warm room over night. When ready for churning it should have a thick velvety appearance and 60° temperature. In summer 56° and 58° is good temperature, but the warmth of the room will have some effect on the cream, and one must be governed some by that. The churn should be a barrel or one similar in construction; it should be large enough to have plenty of room for concussion, thereby lessening the labor of churning.

To color or not to color is a mooted question. When the cream begins to break and form globules the size of large shot, stop the churn, pour in a gallon of water that has had a cup of salt dissolved in it, replace the cover and revolve the churn five or six times Let it stand a few minutes that the globules may rise, draw off the milk, pour in water, wash until the butter is free from milk. Drain well, salt in the churn at the rate of 1½ ounces to the pound of butter, tipping the churn back and forth as you sprinkle in the salt, so that it will be thoroughly mixed. After draining an hour longer, it will be ready to print, working enough only to make the globules adhere. After printing, wrap in parchment paper to exclude the air and dirt. Butter exposed to air soon becomes rancid.

While there is a great deal being done at the experiment stations to establish the theories of bacterial growth and lactic fermentation giving butter its flavor, we believe if the principles herein laid down, of pure air, water and food, and cleanliness, in all parts of the work, are followed, we will have "gilt edge butter".

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By PROF. H. L. RUSSELL.]

Second Series, XII.

COMMUNICABLE ANIMAL DISEASES NOT CAUSED BY BACTERIA.

It is a common belief that all of the various animal and human maladies that are communicable are produced by bacteria. This arises from the fact that a considerable number of these diseases have already been traced to bacterial origin, but the general statement assumes too much. Another reason for this belief lies in the fact that in the minds of many there is no accurate conception of what a germ is. Many believe them to be animals, while as a matter of fact, so far as the bacteria are concerned, they are vegetable.

The phenomena of parasitism, however, is not confined to the vegetable kingdom, and we are beginning to learn that some of the diseases, the cause of which has been supposed to be bacterial are in reality due to parasitic fungi and lower animal forms.

Practically, it is immaterial, whether the cause of the disease is bacterial or not, for if it is due to a living parasite, the introduction of the disease germ is the main factor in the production of the disease. Yet, in other ways, it is of material importance as to what is really the cause of disease, for the biological laws that govern one bacterial disease are almost sure to aid in the working out of the life history of another disease, produced by allied forms of life.

Thus, the methods of work developed in bacteriology in the study of anthrax and tuberculosis have been successfully applied in many other diseases produced by bacteria, but they are not so applicable to those caused by animal and some fungal parasites. Among the more important diseases of this class is lumpy jaw or actinomycosis.

LUMPY JAW OR BIG HEAD.

This disease derives its name from the fact that peculiar tumors are formed on the forward end of the body, particularly the head and neck. This affection which is confined mainly to cattle is more properly known as actinomycosis, and while the parts referred to are most often affected, yet it not infrequently invades other tissues like the lungs and sometimes the digestive tract.

The disease is charactertzed by the development of tumors, which are at first imbeded in the soft tissue and which may later undergo pus formation. A close inspection of the cut surface of these growths will generally enable one to detect minute sulphur-

"I Have No Time to Read."

That is what many farmers say when asked to subscribe for HOARD'S DAIRYMAN. To the man who says it we would say: Note well the man who does read. Consider well his ways. How his mind, well stored with sound knowledge, always goeth ahead of his feet. He is the prosperous dairyman. Go into any creamery and nine cases out of ten the man who has the best herd of cows, who gets the largest yield per cow, WHO MAKES THE MOST MONEY, he is a reader. He takes time to read. He feeds his mind on sound dairy thought as regularly as he feeds his body. Do you know of dairymen who are making money by not reading a good dairy paper? Do you not know of some who pursue the other course and are the more prosperous?

yellow granules that may be readily removed from the tissue. These are masses of the organism that is the cause of the disease.

The germ causing this affection belongs not to the bacteria but to another group of vegetable parasites—one of the lower fungi. It is called the ray-fungus, and hence, the name actino (ray) mycosis (fungus), because under the microscope, these yellow grains are made up of radiating club-shaped bodies.

MANNER OF INFECTION.

The disease germ finds its way into the animal generally by means of the food. It establishes itself in the mouth, if the mucous membranes are lacerated in any way. Sometimes a decayed tooth permits the germ to find its way into the inner tissues, but more frequently the membranes are penetrated by sharp bristles, awns, or hairs from various kinds of grasses. Barley "beards" and the pointed awns on our common squirrel tail grass, which is a botanical relative of the barley, not infrequently serve to introduce the germ.

While the disease is in the strict sense of the word contagious, because it is produced by contact with the diseased material, it is not readily transmitted from animal to animal like anthrax or even tuberculosis.

If, however, an animal is affected with actinomycosis, care should be taken in regard to the distribution of the material discharged from the tumors. These contain the disease-breeding germ, and thereby the liability of infection is consequently increased by the presence of an affected animal, unless the discharges are properly treated.

The presence of the distintive germ of the disease is sufficient to cause an irritation of the invaded parts that results in inflammation, and the characteristic bunch is formed in those tissues that are near the surface of the body.

The character of these tumors may vary much in consistency. Often they are soft and quite yielding to the touch, but as the foreign growth increases in dimensions, they frequently take on a firmer character, that is due to the development of fibrous tissue.

Inasmuch as the disease generally results from invasion of the mouth, through its mucous surfaces, the tumors develop in the tissues that are contiguous to these surfaces. The salivary gland at the angle of the jaw is very frequently affected; then again, the disease may attack the bony system of either jaw.

In this case it is more serious as the development of the fungus results in the deformation and ultimate destruction of the bony tissue itself. In the later stages of the disease as the swelling increases in size, it may break through the outer skin, in which case thick yellow pus is formed.

Sometimes the disease affects the tongue, causing this organ to lose its flexibility. Hence, the distinctive name, wooden tongue which is applied to this phase of the disease. If the actinomycotic organism is drawn into the lungs with the air breathed, it is possible that the disease may establish itself in this tissue. The course of the malady is, however, quite similar, abscesses being produced.

To the casual observer, this phase of the trouble might be confounded with tuberculosis, but by a careful inspection it is possible to distinguish it from that disease as the yellow grains that are so characteristic of lumpy jaw can generally be seen with the naked eye.

The development of the disease is apt to be quite slow. Where the bony tissues become involved, the destruction of the same may interfere seriously with the ingestion of food. Respiration may be obstructed, if the tumors develop in connection with the pharynx. Where the trouble is near the surface, and does not directly affect any of the vital functions, as breathing, eating, etc., no serious impairment of the general health of the animal is apt to occur.

COMMUNICABILITY TO MAN.

Actinomycosis also occurs sparingly in man (only 58 cases have been reported in America) and it is a question of considerable importance as to whether the human being may not contract the disease from the bovine, in which species the disease is quite prevalent.

The evidence on this question is far from conclusive, although some cases are on record in which it seems more than probable that human beings acquired the disease from animal sources.

The idea is still prevalent in some sections that all meat from an animal affected with lumpy jaw should be regarded as unwholesome, but it is manifest that such a measure is altogether too sweeping, and that there is no warrant for the total destruction of such meat. The extent of the lesions and the location of the same should be taken into consideration in determining the disposition of the carcass.

TREATMENT OF THE DISEASE.

The loose tumors that develop in the fleshy parts of the face and neck can frequently be cured by a surgical operation. This treatment, however, cannot well be given where the disease becomes established on the jaw or tongue, or in the internal organs. Within recent years a new treatment has been found that has proven very successful. It is the administration internally of iodide of potassium.

The dose given should vary with the weight of the animal, and is about one-fourth dram (1 gram) per cwt. of live weight. The continued use of the drug will result in symptoms of iodism, which is characterized by discharges from the nose and eyes, and scaling off of the skin.

These symptoms will be alleviated by a discontinuance of the drug, and after having disappeared, the use of the remedial agent can be resumed. The remedy is not of so much service with milch cows, as the milk is rendered unfit for use during treatment. The proper use of the drug seems to dry up the tumor rapidly without any ill effect on the animal.

Co-operative Creameries.

ED. HOARD'S DAIRYMAN:—In reading Mr. George E. Scott's article, "Why Creameries Do Not Pay," in the DAIRYMAN of March 24th, I was somewhat surprised to find that co-operative creameries in Ohio are not a success.

Is it possible that we have more intelligent farmers in western Wisconsin and Minnesota than in Ohio? Sixty-five per cent of the Minnesota creameries are co-operative and successful; here in western Wisconsin the majority are co-operative, and they are driving out private creameries.

I do not know of a single instance of a co-operative creamery failing. We have no trouble to pay as much per pound for butter as the private creameries, and at the end of the year, we have always paid a dividend of at least ten per cent on our capital stock. Our neighboring co-operative creameries have paid from 7% to 10% dividend each year, besides improving our plants.

Mr. Scott speaks of one factory "that went into debt head over heels, by the use of a popular butter calculator in making out churn gains from fat tests, when there must have actually been little or no churn gain."

Now the management of this factory must either have been very careless or very dull, to have let this state of affairs happen. If the affairs of the creamery are run as they should be, it is an utter impossibility to run the creamery in debt on this score.

After we get in all of our sales for the month, we simply deduct the sinking fund and expense for the month, and the balance is divided according to the number of pounds of butter or butter fat. To say that the co-operative creamery cannot be run as cheaply as the private creamery, I think is a mistake.

Mr. Scott says "that the owner of a factory in his locality, by batching it and getting a boy to help him, was making a success of the business." How long do you think this owner will be satisfied to work this way?

As a rule, the owner does not do the work, but hires some one as butter maker, and expects to make enough out of the business to pay him a good interest on the money invested. Now, why not let the farmer take this interest, and manage his own affairs? We farmers raise our cows, feed them, do the milking, and take the milk to the creamery, can't we finish the job by making and selling our butter? I think we can.

Stock in a co-operative creamery in this locality is as good as wheat, as there are always buyers, if any is offered for sale.

Mr. Scott speaks of co-operative creameries having failed because the patrons did not supply the milk necessary. Any creamery will fail if they do not get milk enough; that is the all important point. Creamery supply concerns in the past have built creameries in sections where they could get the necessary stock subscribed, when there was not enough cows in the locality to support a creamery.

All such of course failed, but where there are enough cows to support a good creamery, the co-operative is the best, as we cannot ask any more than all there is in the milk, after paying for the making. Hire a first-class buttermaker and run the creamery on business principles, and there is no chance for failure. DAVID IMRIE.

Buffalo Co., Wis.

Improving The Herd.

ED. HOARD'S DAIRYMAN:—I am going to let you know what reading HOARD'S DAIRYMAN has done in my herd. I came into possession of ten milch cows last March. After reading the DAIRYMAN and seeing the difference in cows, I bought a Babcock tester and scales, and the milk was weighed night and morning, and tested twice a month.

The first cow, I weighed her milk as soon as it became good. The next two calved on January 28th, next two on February 1st. All these were weighed from March 20th only, so can not do them justice.

The rest of the herd calved after I began weighing. I sold the five poor ones, and have bought six high grade Jersey heifers of the St. Lambert strain.

No. of Cow.	*Lbs. of Milk.*	*Butter by Test.*
1	7,840	313
2	7,230¾	289
3	5,738	229
4	5,752¼	249
5	5,442½	236
6	2,834	177
7	4,751¼	166
8	4,538	159
9	3,669¼	156
10	4,405	154

No. 6 is a thoroughbred Jersey two-year-old. I milked her from June 15th to Feb. 3rd. When I sold her, she was still giving eight lbs. per day. No. 10 was a high grade Ayrshire, two years old. The rest were from five years up to ten years old, and the five best are of the special-purpose type.

Under good hands, this year, they will make more butter.

In answer to the Editor's Questions:

1. Yes.

2. 10 cows, tested for ten months. Rejected 5.

3. Cost $6 for scales, $10 Babcock tester. Took sample from two milkings, twice a month. The trouble and expense is not to be compared to feeding five useless cows.

4 No, but have a thorough-bred Jersey bull, Mac of Lynwood, now.

5.

6. Breed in the same line by all means.

7.

Ormond, Ont. E. D. B.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of supplying animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gum and in the published tables of chemical analysis are usually subdivided into the terms *crude fibre*, which is the least digestible portion of these stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passes on into the circulatory system in a changed form, or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained by some, that the fat in the milk comes, largely, from the crude fat in the food, but it has been demonstrated that it is not absolutely necessary for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

SEEDING TO GRASS.

Can I get a good seed catch after oats and peas where it is cut for green feed early?

Binghamton, N. Y. E. J. L.

Much will depend upon the variety of seed sown. It is hardly possible to sow clover too early. Indeed not a few farmers insist that the best time is when there is snow on the ground. Clover is not a very hardy plant at best, and the better it is established the less will be the danger of winter killing. And yet we have known late seeding to be very successful.

The better practice in all cases is to keep something growing on the land all the time. It pays to sow clover in the corn field at the last time of cultivating, and turn it under late in the fall or the following spring. Crimson clover is especially adapted to this purpose.

A UNIVERSAL REMEDY FOR UDDER TROUBLES.

Mr. Herman Whitaker, of New Hampshire, in renewing his subscription to the DAIRYMAN, writes as follows: "Tell the readers of the DAIRYMAN that a free and persistent use of Snow Flake Axle Paste will cure about all the ills that a cow's teats and udder are heir to. Sore teats, scab on end, bunch in the teat, hot and inflamed and caked udders have all yielded to its persistent use."

We are very much obliged to Mr. Whitaker for this bit of experience, and would add a confirmatory note from our own. We have found common axle grease to be a very excellent remedy for many of the ills to which both cows and horses are subject. We can hardly go as far as our correspondent does, in saying that everything will yield to its persistent use, but we have found it quite as satisfactory as any other single remedy.

AS TO BEEF BRED COWS.

How to feed a herd of beef bred cows so as to get a paying flow of milk and not allow them to take on any fat? Is it high feeding and good care that would cause a 3-year-old heifer to go wrong, be always in heat, roam the fields and bellow, when she was sired by

a neighborhood bull that knew no fence or farm? Is 9,763 pounds milk and a veal at $7.50 cash in 10 months, 3 days, a common yield from common care from a beef bred cow? W. B. T.

Standing Stone, Pa.

We have substantially answered the first query above in another place in this issue, to the effect that when any milch cow, no matter what her breeding or classification, commences to lay on superfluous fat, the amount of fat forming feed given her—the carbohydrates and fat—should be curtailed, and the muscle and milk forming feed, that is, the protein, may probably be somewhat increased. Whether this will result in securing a "paying flow of milk" cannot be determined in advance. Moreover, there are different opinions as to what is a paying flow of milk. Our opinion is that it does not pay to keep a cow giving $15 net income very long when it is possible to have one that will yield $20 or more net income. In other words, "The best is none too good."

The second query does not admit a specific answer. High feeding frequently produces the conditions named, but not always. Individuality is a potent factor in all directions. There are very few beef bred cows, even with extra care, that will yield 9,000 lbs, of milk in 12 months.

CASEIN IN POOR AND RICH MILK.

Remembering that butter milk and loppered milk sell for ten cents a gallon, will it pay us to keep a few Holstein cows, i. e. is there any considerable difference in constituents of closely skimmed 3% milk and 5% milk? Will not the latter go nearly twice as far for feed for calves and pigs and for cottage cheese? W. BROS.

Humboldt, Tenn.

Three per cent milk contains about 2.9% of casein and albumen; five per cent milk in the neighborhood of 3 7% of casein and albumen. The milk sugar remains more nearly constant; the variation bring less than three-fourths of one pound between three and five per cent milk. The feeding value of three and five per cent milk, aside from fat, would be in the relation of 8 to 9.50.

For the making of cottage cheese, the richer milk is more valuable in the ratio of 3.14 to 2.10, as only the casein can be used for the above purpose.

It would not be advisable to raise a cow for the purpose of producing casein, without considering the fat; at present skim milk is a waste product, or rather by-product of the dairy, and one that can be obtained at a very low price.

Circumstances may be such, that in your case skim milk brings more than its usual price, but in such event, it would be better to breed towards a good flow of rich milk, and thus obtain two values from the food, rather than endeavor to increase the amount of the cheaper ingredient; at the same time, breeding up a herd of low monetary value.

SILO QUESTIONS.

1. What objection is there to the ground for foundation and floor for a stave silo?

2. Where we wish to build our silo, the rock is within one foot of the surface. How would it do to put bottom of staves on this rock?

3. Can a small cutter and a 30-foot elevator be run with a two-horse power? If not, how much power is required to operate one?

4. Give dimensions of a round silo sufficient for twenty cattle, 180 days.

5. Tell us how to build a round stave silo on a cheap and durable plan.

6. If menstruation comes on a cow after being served by bull, is it not evidence that she has failed to concive. W. AND SON.

Benham, Texas.

1. There is no objection if the ground is of clay or a clay loam. If of sand or gravel, it lets in too much air, and the silage spoils at the bottom. The foundation of the silo should be as air tight as possible.

2. All right, if you can make the stave bottom tight; otherwise use cement or clay.

3. Yes, if you don't try to cut more than fifteen tons per day.

4. It will take 72 tons, requiring a silo 16×21 feet.

5. See last issue of the DAIRYMAN, page 187.

6. If it is repeated, yes.

SOILING CROPS.

Please inform me as to time of planting, amount of seed per acre, amount of each crop, and best crops to plant to feed thirty head of cows from June 15th, to November 1st,; feed to be cut and hauled on meadow for cows. H. R.

Woodbine, Pa.

On page 129 of the current volume, will be found a table giving crops, areas, seed and time of planting for soiling crops.

CURE FOR LUMP JAW.

Is there any cure for lump jaw on cows? What is it. R. T. F.

East Rochester, O.

See article by Prof. Russell in this issue of DAIRYMAN.

DAIRY CHURN.

Will you please tell me the best kind of a churn to use for a dairy of ten cows. C.

Kendallville, Ind.

Any of the revolving box or barrel churns will do.

ARE SILOS DANGEROUS?

I send you herewith, a clipping from the New Castle *News*, on the silos that I think will do a deal of harm. We have several dairyman that talk of building, and this will knock them out. A number of them have taken the DAIRYMAN this spring. Please give me your opinion on this question.

New Castle, Pa. F. E. MC A.

We have received several copies of the same cutting, from papers in different parts of the country. We don't know what kind of material there was in the silo, but if it was corn ensilage, there was certainly nothing formed that could kill, or cause the illness of any animal. There are thousands of men, working in silos, getting out the feed for their cows, every day this winter, with no thought of illness of any kind.

Moreover, meningitis is not a disease of the lungs, but of the brain and spinal cord, and could not be caused by a gas. It is much more probable that the lung affection was caused by the ammonia from fermenting horse manure.

BOOK ON DAIRYING.

Can you tell me through the DAIRYMAN where I can get a good, practical book on butter making? Find enclosed one dollar for 1899. E. D. B.

Ormond, Ont.

We would suggest Gurler's American Dairying. It can be obtained from this office, post paid, for one dollar.

RULES FOR OFFICIAL TESTS OF JERSEY COWS.

I am a new subscriber to the DAIRYMAN. Have a small bunch of A. J. C. C. cows. I see that bulls are advertised as having so many in the list. Now what I want to know is how to make a test, that is, an official test, one that can be recorded.

I have a cow that has made 14 lbs. butter in seven days. I also have a two-year-old that made, the week she was two years old, 9¾ lbs. butter in seven days.

I fed the two-year-old 4 lbs. bran, 4 lbs. ground corn, 1 lb. flax seed meal, 24 lbs. sugar beets, and all the sorghum fodder she would eat. Drink, cold water. Stabled at night and run in the yard through the day. She had been in milk two months Is this a fair showing for a youngster?

Blais, Neb. A. C. J.

Write to Secretary American Jersey Cattle Club, No. 8, West 17th St., N. Y., City, for a copy of the rules governing official tests.

The heifer's record reported above is certainly a very good one, but in our judgment she was not fed to best advantage for making a large yield. The digestible protein in her daily allowance of feed did not exceed two pounds, whereas, for best results, at least for a short period, it should have been certainly not less than 2.25 lbs. and very likely she could have used more to good advantage. The linseed oil meal of commerce would have been better than the ground flax seed. It should have been fed up to at least 2 lbs. daily. In the absence of this oil meal the bran should have been increased nearly or quite 100 per cent and the corn meal correspondingly reduced. It should not be forgotten that protein is the one indispensible thing to enable the cow to make milk.

VALUE OF FAT IN MILK AND CREAM

What is the proper allowance for separating cream at home for sending to a creamery? J. D. O.

Victoria Co., Ont.

We do not exactly understand what you mean by "allowance" but assume that it is the extra value which fat in cream has over fat in whole milk; owing to the absence of loss in separating.

The loss of fat in skimming is from 3.5 to 4 0 per cent of the total amount of fat present when good work is done with the separator. Thus a hundred pounds of fat in 25 per cent cream is equal to 104.0 pounds of fat in the form of 4 per cent milk. On one hundred pounds of milk this would amount to a fraction over three cents.

THE SAND VETCH.

Would you be kind enough to give your views of the value of "sand vetch" advertised in DAIRYMAN, March 3, 1899, by Currie Bros., compared with clover as a forage crop, for hogs, and also in regard to enriching the soil? C. E. S.

McKinstry, Md.

We find very little concerning this particular species of vetch in any of the books or bulletins, and conclude, therefore, that its comparative value as a forage plant is not fully determined. In South Dakota the vines grew to six feet in length, and were so rank and thick, that the crop could not be cut with a mower, and had to be harvested with a scythe. When introducing new varieties of grains or forage crops in any locality it is not wise to commence on too large a scale.

CUBIC FEET IN A TON OF SILAGE.

How many cubic feet of ensilage are there in a ton? W. H. M.

Salem, Ohio.

The weight of a cubic foot of ensilage will vary according to position in the silo and the amount of silage above it. In a silo 36 feet deep, the first foot will weigh 18.7 lbs. and the bottom foot 61.0 lbs. per cubic foot. The average weight is about 40.0 lbs. per cubic foot, this would be 50 cubic feet to the ton.

SALTING AND WORKING BUTTER IN A SWING CHURN.

I have seen some very interesting articles in your paper on salting and working butter before removing it from the churn so it will require no second working. It seems very practicable for those using revolving churns. How may the same result be obtained in the Davis Swing churn?

Lincoln, Ill. S. E. D.

To work and salt butter in the churn it is necessary to use a revolving churn so that the butter and salt would have fall enough

"Necessity Knows No Law."

But a law of Nature bows to the necessity of keeping the blood pure so that the entire system shall be strong, healthy and vigorous.

To take Hood's Sarsaparilla, the great blood purifier, is therefore a law of health and it is a necessity in nearly every household. *It never disappoints.*

Tired Feeling – "I had that tired, dull feeling, dyspepsia, headaches and sinking spells, but Hood's Sarsaparilla made me a new man. I never was better than now." JOHN MACK, Oskaloosa, Iowa.

to be thoroughly mixed. We rather doubt the possibility of the same results being obtained in the swing churn.

A NEW YORK RATION.—FEEDS DISCUSSED.

Enclosed please find post office order for $1 to renew my subscription to HOARD'S DAIRYMAN; please give me credit for same and oblige. The DAIRYMAN has done wonders for me. I think it is the best invested dollar I ever paid out.

I wish you would formulate a ration for me in your next issue out of the following: Ensilage, bran, barley meal and timothy hay. My ensilage is heavily loaded with corn. Cows are of ordinary size. C. K. F.

Fillmore, N. Y.

About the best that can be done, if one is limited to the feeds mentioned, would be the following:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
30 lbs. silage	7.92	.39	4.20	.21
8 lbs. timothy hay	6 92	.22	3.46	.11
6 lbs. bran	5.39	.75	2.32	.18
6 lbs. barley	5.35	.52	3.94	.10
Totals	25.58	1.88	13.92	.60

This gives as much dry matter as the cows would be expected to eat, and contains, if anything, a surplus of carbohydrates. It is, however, deficient in protein and we should prefer more fat. The question therefore is, how to obtain more protein and more fat without unduly increasing cost. By turning to the feeding tables it is found that cotton seed meal, gluten feed, linseed oil meal, peas, malt sprouts, and buckwheat middlings rate particularly high in protein. We should therefore try to substitute some one or more of these feeds and reduce the amount of barley particularly, and perhaps bran to some extent. If we take out one pound of bran and one pound of barley and substitute one pound of cotton seed meal, we have the following results:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
Silage and hay as above	14 84	.61	7.66	.32
5 lbs. bran	4.41	.63	1.93	.15
5 lbs. barley	4 46	.44	3.28	.08
1 lb. cotton seed meal	.92	.37	.17	.09
Totals	24.63	2.05	13.04	.64

If the barley can be sold to good advantage, it might pay to exclude it altogether and substitute gluten feed. In that event we would have the following figures:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
Silage and hay as above	14.84	.61	7.66	.32
5 lbs. bran	4.41	63	1.93	.15
5 lbs. gluten feed	4.61	1.02	2 42	.25
Totals	23.86	2 26	11.51	.72

The last formula seems to us better adapted for cows that are fresh, or nearly so, than either of those preceding it. It conforms very closely to the so-called American Standard Ration for milch cows. For cows giving a large quantity of milk the protein should be rather increased than decreased. This can be effected by increasing the gluten feed or adding from ½ lb. to 1 lb. cotton seed meal. We omit linseed oil meal, partly because of the extravagant price at which it is sold and partly because we do not consider it specially necessary when there is succulent feed like silage, roots or pasture.

COOLING CREAM—SEPARATORS.

We finish separating at noon, do not cool cream from separator, hold it at 68 or 70 degrees, find it 65 degrees the following morning, thick, and the right acid as per Farrington's test. We then churn at 50 degrees, the cream being rich enough to average four pounds of butter per gallon. The buttermilk is thin and tests clear. Now the butter is fine, but would it be better if we should cool the cream as it comes from the separator and, if so, how cold? We also use ice in the churn for cooling from 65 to 50 degrees.

Can you suggest another or better way to cool thick sour cream? We have the twin cream vats with a coil of 4, 1¼ inch pipes running lengthwise of the vats. These are connected with the Remington refrigerating machine but it takes so long to cool in that way.

Is there a separator made that is superior or equal to the Alpha DeLaval?

Ill. E. P.

In handling cream, much depends on the water supply. For instance, if you have a good supply of water below 50 degrees, we should not advise you to use ice in the churn. There is too much dirt in the average ice to make it a good addition, in any form, to either cream or butter.

It is tedious work to cool cream in a body as it is in cream tanks. It is both cheaper and better to do the cooling at the time of separating. By running a stream of cold water or brine through an outside cooler, the cream can be brought to any required temperature and much time saved.

To obtain the best grain and body, especially in hot weather, it is necessary to hold the cream at or below 50 degrees for at least four hours.

It makes little difference when this is done, whether just after separating or before churning. The time is a question of convenience, but as it is easier to handle sweet cream, it would probably be best to cool direct from separator.

We cannot assume to decide upon the relative merits of rival machines, whether separators, combined churns and butter workers or self binders.

SUGAR BEETS FOR COWS.

What kind of sugar beets would you plant as feed for milch cows? What do you think of alfalfa? J. M. S.

Richmond, Ind.

It will not pay you to grow sugar beets *exclusively* for cow feed. If given in large quantities they cause scouring.

Mangles are easier grown and harvested and are better for the cows.

Alfalfa is one of the most valuable known foods for dairy animals. Its value is too well understood to require any discussion.

THE RENOVATED BUTTER QUESTION.

THE Minnesota Dairy Commission is after renovated butter with sharp sticks. A new food law is before the legislature supported by the Commission which will deal with this product rigorously.

Concerning the article the Commissioner says:

The manufacture of it is in this wise. The greasy, smelly, frowy butter is first melted and then mixed with air by running it through a separator or by pouring it through a sieve and letting it fall a considerable height. That takes the taint away and leaves it clean and sweet. Dropped into water it granulates. Then it is mixed with skim milk; a lactic acid ferment, of laboratory manufacture, is added—the same comes of itself in making butter—and the mixture is churned and salted and made up into pats of best creamery butter.

And what harm? Experts say it won't keep any time out of the refrigerator. It loses its consistency and relapses into grease. It loses its flavor and resumes its flat taste.

To prevent that, preservatives are added, —borax, boracic acid, salicylic acid, formaline and the like. The preservatives kill the germs in the butter and keep it indefinitely in the condition in which it came from the factory.

If the preservatives could be taught to discriminate in their duties, renovated butter might be a fairly good substitute for creamery. But they go on germiciding to the end of the chapter. And it happens that digestion is a process in which certain germs assist. Of the several hundred species of bacteria and microbes that dwell in the human body some are necessary to nutrition. So the preserved butter may be indicated in the household by internal dissensions

"These preservatives," says Assistant Commissioner White, "are not immediately poisonous, but in time they are bound to impair the health and may work fatal injury. They are used a good deal in milk, too, more now than we could wish though a good deal has been done to stop it.

"I don't know that renovated butter is unwholesome without the preservatives, but it won't keep, and it is a fraud if it is sold for new butter. With preservatives it is distinctly unwholesome.

"There is one establishment in St. Paul, one in Minneapolis and one in Duluth where it is manufactured. It is done on a smaller scale in some other places. I know of one creamery which has turned from making butter to making it over."

Blackleg.

Treatment—Prevention.

Blackleg is characterized by its rapid and almost invariably fatal course. As is the case with all similar diseases, the public is imposed upon by uncrupulous quacks, who make and sell all sorts of sure cures for blackleg. The principal characteristic of all these so-called remedies is that they fail to do what is claimed for them. We mention some of the remedies below, viz: The internal use of salt, hellebore, assafœtida, nitre and sulphur; the application to and under the skin of pink tablets, ointments, elderpith, onions; surgical operations, like setoning, roweling, nerving, bleeding, the running of animals, etc.

It is a fact that, in some instances, the use of some of these remedies is followed by a decrease in the number of deaths, and sometimes animals stop dying altogether, as if by magic. But these are single observations and they prove absolutely nothing. We can find just as many similar instances where no treatment whatever is followed.

We know that thrifty calves are more likely to be attacked with blackleg than unthrifty ones, and that, once attacked, the former seem to have the least chance of recovery. It has, therefore, been suggested to observe care not to let animals get too thrifty; this is easily done, either by resorting to the time honored but now slightly out of date practice of bleeding, or by giving purgatives, or by actual starvation. If anyone sees economy or profit in this procedure he is advised to follow it.

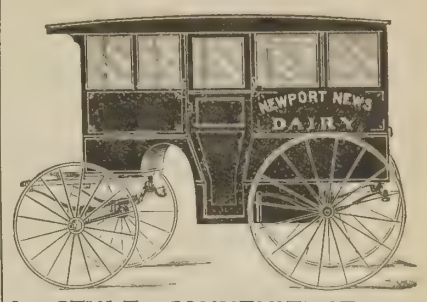
We believe in prevention. The cause of blackleg in calves is two-fold: First a natural susceptibility of the animal to acquire the disease; and second, the blackleg bacillus, a microscopic, vegetable parasite belonging to the bacteria, the excitors of most of the common infectious diseases.

Blackleg is caused by the blackleg bacillus, and by no other germ. On the other hand, the blackleg bacillus causes blackleg and no other disease. By controlling this bacillus we would have one solution of the question of prevention.

Blackleg is a wound infection disease, i. e., it is produced by infection through a wound; by the entrance of the blackleg bacillus through a wound into the body tissues This wound may be in the skin or in the mucous membrane of the digestive tract (mouth, stomach, intestine).

Blackleg bacilli are found in two places—in the bodies of dead or diseased blackleg victims, and in certain low, damp soils, usually bottom lands. In both places these germs grow and multiply. Infected soil, or food plants grown on such soil, serve as means to carry the germs into the animal's tissues. Wounds or bruises in the animal's skin or digestive membranes, be they ever so slight, serve as ports of entrance for the bacillus. The hoofs of animals and their coats of hair, even their droppings, carelessness in attendants, serve to carry the germs from place to place.

These statements point out two possible methods of prevention:



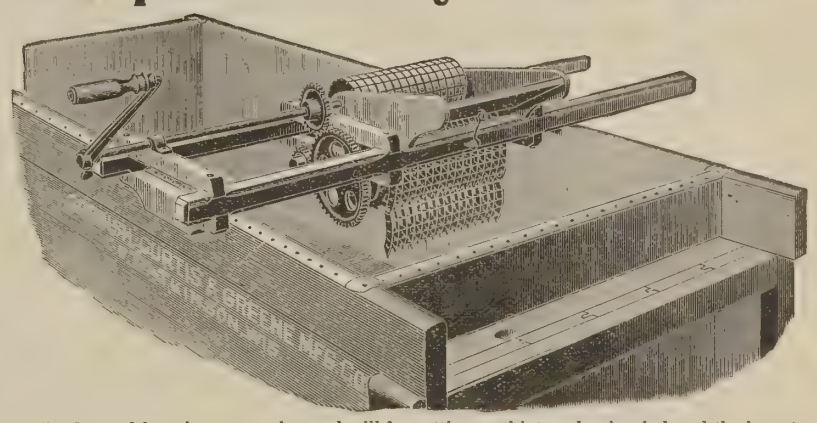
(1.) Changing animals from infected fields (usually low places with rich soil) to non-infected grounds (high, dry places).

We can further prevent the spread of the disease, by burning the dead bodies of animals that died of blackleg, avoiding the practice of burying such carcasses, which amounts practically to planting the disease germs for future harvest.

(2.) The disease can, in a measure, be prevented by proper feeding. Feeding digestible grasses and root crops, avoiding rough cornstalks and other coarse, hard foods which can produce small internal or external wounds or abrasions, and thus provide a port of entrance for the disease germ. The germ always enters the body through a wound. Suckling calves do not have these opportunities for wounding their delicate mucous membranes, and it is a well-known fact that they are rarely afflicted with this disease. However, this is not the only explanation for that fact.

So much for prevention by guarding against an invasion by the blackleg bacillus. — *Kansas Experiment Station, Press Bulletin.*

The World Cannot Show Its Equal



In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairymen at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

Note and Comment.

Feeding Silage and Corn for Milk Production—Balanced Ration an Exception to the Rule.—City Cream Trade.—Gouda Cheese.

ED. HOARD'S DAIRYMAN:—One of the strangest things that is "at large" is the utter contempt some dairymen exhibit towards trying to feed their stock with some degree of skill, now that practical instruction is to be had from authoritative sources. A farmer who is milking a winter dairy, has a good barn, a silo with fine silage, complained that his cows were not giving as much milk as they ought, in fact, but a little more than when farrow.

He said he was feeding them all the silage they would eat, of well eared corn, quite a feeding of hay, and twelve pounds of corn and cob meal to the cow. It was no use to tell him. He knew that corn meal had no equal to make milk and butter, and ought to fatten a cow at the same time; but they are not fat, and——and——and——that was the end of men telling him that cows could be milked and fattened at the same time. It had cost him a thousand bushels of corn to find out that one should not believe all these college farmers told, and away he went.

***

Last evening neighbor Burnett—some ten miles away—called me up over the telephone to tell me what a great help the new Cornell Bulletin No. 154 had been to him within the past month. He had been feeding a certain combination of grains with his silage, and thought he was doing a pretty fair up to date job, but he got hold of this bulletin, and taking his scales he weighed out accurately the ration that he was feeding, and found that it was very short in protein after all.

So he figured up the cost of this ration, built another one according to the book, and found in a week that his thirty cows were giving about 75 pounds more milk a day—83 cents worth—and the feed was costing him a cent less than the first one.

He was feeling good over the affair and together we planned another silo, to be filled next fall for 1900 summer feeding. Here was the difference in two men. One knew, and fed twenty pounds a day of digestible starch, etc., fuel makers, when his cows only needed fourteen, and but litttle of the protein which they should have had to supply the needed milk stimulant, body action and blood and nerve food; threw away 1,000 bushels of corn, and got far less milk. The other man thought he was wrong, took pains to inform himself, and is making a profit of $1.12 a day by it. Still there are those who will "call him down" and still say, "Great is Diana of the Ephesians," and go right on feeding timothy hay and corn meal, and kill hogs by the moon.

***

Not long since at Piqua, O., at an Institute, I came across one of those confounding things which are created for the express purpose of proving a rule by being a conspicuous exception, and it was an exception to show that once in a great while, milk and butter are combined in great quantities in an animal that does not exhibit any marked number of "signs," or conform to the dairy type or temperament.

The cow in question is the property of Mr. Cox, of that place, and is his only cow, so there was no chance for him to carry her milk through the spring house where other milk was creaming. The cow in question is possibly a 1,300 pound cow, of some Shorthorn blood, the balance being the Ohio mixture of all breeds; huge head and horns and remarkably devoid of nervous energy. But her butter making powers are great.

In the year 1896, she gave milk from which was made and sold 686 pounds butter, and the skim milk fed to a calf that was sold for $25. During the year, besides the grass on a small lot, she consumed twenty bushels wheat, fifty-five of oats, and twenty-five of corn ears, together with two tons of clover hay, all costing $37.50. The butter sold for $137.00 (20 cents per pound) and with the calf made her income $162.

The next year on practically the same food, but less cost, this cow made 760 pounds of butter which was sold for $152, and the calf for $5, making $157, but the skim milk was not counted. The highest amount of milk given in one day was 52 pounds, and the most butter made in one week was 19 pounds, but the great total amount was made in persistent yield for the year.

The old gentleman puts his hand over the old cow's neck and with no little pride remarks: "She izen't none of yer blooded critters, but when it comes to producin', she makes them thoroughbredded animals strike a purty lively stride, to go with her."

***

The producing of cream for the city markets is making its effects seen in many ways in northern Ohio. It is not only stimulating the price for milk, but is reviving the industry itself, and cows are selling for old time war prices. There is a result growing out of it that is not so commendable, and that is these cream concerns are about all making the skim milk into cheese(?) and as it is selling in Cleveland at 7 to 9 cents per pound, between cream and cheese the milk buyers are not losing anything in 11 cent milk, i. e. 11 cents for 10 pounds of milk.

The outcome of this may not add any laurels to the reputation of Ohio cheese, or cut much ice in competition with Canada, but in the light of the ever omnipresent dollar, it seems the thing to do, though the end will probably be the apples of Sodom, and these skims will later on pull down a lot of good cheese with them. Some of these concerns use the deep pails for milk setting, and of course there is some fat left in the milk, and less pepsin will be needed to digest the cheese but some of them will prove durable enough to utilize as handy wagon wheels.

***

In the Gouda section, I notice there is an increase being made this season in the Gouda cheese business, four large factories with a combined daily supply of nearly 50,000 pounds of milk per day, is all being made into full cream Goudas, and shipped as fast as they get a full (?) flavor. While the demand for these peculiar cheese is increasing, the demand about how they shall be made, is now different, and they are now made salter, more solid, more taste and other reminders of Holland.

They are now left longer in the brine, so that the salt will strike to their very centers. The utmost care is used in making them so that there shall be no loss of fats, and some whey that was Babcock tested, only showed .1%. The curd is slightly scalded and salted some before pressing, but the cheese get most of their salt in the salt baths, which are as salt as they can make them, with more salt added. They are cured in cellars and mould is not objected to. When the cheese are packed it is well brushed off, and start for market with bright faces.

Ohio, April 16th. JOHN GOULD.

Stave Silo Queries From Iowa.

ED. HOARD'S DAIRYMAN:—I am contemplating building a silo this summer and I wish to ask you a few questions to be answered through your most highly esteemed paper.

The size I wish to build is 25 ft. in diameter by 25 ft. high. Now, will ensilage keep as well in as large a silo as this as it would in a smaller one, and would it not be better to have the staves all the full length than to have them spliced? My plan is to put a good stone wall laid up with cement, say about one foot thick and 18 in. deep, with about 6 in. of it above the ground, then fill up nearly to the top of the wall with gravel or cinders, also have a tile laid so as to drain, then use 2×6 spruce or fir dressed on one side, tongued and grooved for the outside wall. Then after getting this set up and hooped with flat hoops (which I want you to tell me the size iron to use and how many it will take) I will commence at the door and put on a strip of tar paper then cover with good flooring of the same kind of wood and line it.

Then I will cover it with cedar shingles making it a circular form. Now, as to a ventilator, does it need any or not? I will give it 3 good coats of paint on the walls

What do you think of my part of the plan, and how much will it hold, or how many cows will it accommodate? I have about 75 head, old and young

I also ask your opinion of a half-bred Jersey heifer that was 20 months old when she dropped a calf, a heifer, and although I milked her twice a day for a month she did not give a bit of milk. I re-bred her, is she likely to do the same again? She was fed corn fodder with corn, oats, straw, clover and timothy hay, do you think her heifer calf will be a failure?

I have been a subscriber to your paper over a year and I consider HOARD'S DAIRYMAN one of the most useful things in my business.

Any suggestions or answers in the columns of the DAIRYMAN will be very acceptable.

Wappelo Co., Iowa. J. B. B.

A circular silo 25 ft. in diameter and 25 ft. high will hold approximately 225 tons of silage. This will suffice to feed 75 animals 200 days at the rate of 30 lbs. per day, or longer, if less is fed. The trouble with a silo of this size would be that the feeding surface is too large. More or less of the silage would be injured by exposure from day to day. It would be a little more expensive, but on the whole, a little more economical, to build two silos, each 16 to 18 feet in diameter. Feed from one until it is empty and then from the other.

It is an entirely useless expense to use long joists for such a silo. Lumber, 25 feet long, costs a great deal more than that which is 16 feet or less, and is absolutely no better for building a stave silo. Ensilage keeps as well in a large silo as in a small silo, except as above stated. Six square feet of surface, per cow, is as much as should be uncovered at one time. That is to say, if a man has twenty cows, his silo should not be so large that he would be obliged to uncover more than 120 square feet. Where flat hoops are used they should be from 2 to 2½ inches wide, and not less than 5-16 inches thick, and a silo 25 feet high should have not less than seven of these hoops, one at the bottom, another 2 feet above this and the third 3 feet above the second, and so on. The pressure at the bottom of the silo is much greater than at the center or the top, therefore the hoops should be closer together at the bottom. Notice the construction of the water tanks at railway stations, and see how this law is observed there.

A silo does not need a ventilator at the top of the roof, although one would do no harm. For inside of the silo, there is nothing so good in the way of painting as coal tar, but paint of any description should not be applied until the lumber is thoroughly seasoned through and through. Nothing will induce decay sooner than to paint lumber before it is thoroughly seasoned.

In regard to other details of construction mentioned, no particular criticism, either in approval or disapproval is necessary. A good many people would say that the interior lining is unnecessary, others would approve it. It certainly would do no harm, and its tendency would be in the direction of making the structure more impervious to air. It would be necessary, however, if this method of building was followed, to thoroughly coat the inside lining with the coal tar paint, and to renew it as often as necessary.

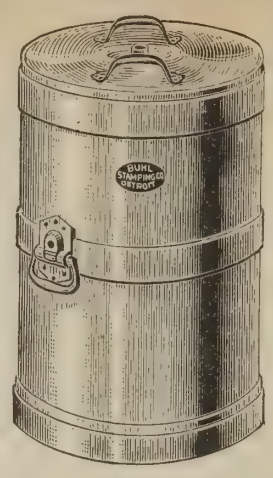
The case of the heifer referred to is so very unusual that we hesitate to express an opinion. It is at least doubtful whether she will ever make a profitable cow. The probabilities are that her heifer calf may not take after her in this respect, but there is an element of uncertainty in this respect, and on the whole we should be disposed to prefer not to run the risk.

Breed and Form.

ED. HOARD'S DAIRYMAN:—If you think this worth printing do so, if not, let the waste basket have it.

I read both the DAIRYMAN and the *Jersey Bulletin*, which claims there is no cow equal the Jersey, and the DAIRYMAN any breed, so she is of a dairy form. My experience has been that you do not get the dairy form without either the Jersey or Guernsey blood. We have lots of good cows in the country which do not look like either breed in any way, but I feel sure the blood is there. Well do I remember the first cow I bought; she did not look like anything but a native, but with good feeding and care she would make 10 pounds of butter in 7 days, and furnish the milk used in the family. She was of the dairy form, and I have since learned she got it from the Jersey blood.

There is a great objection to the Jerseys in this county on account of their size, but I have cows of that breed that will weigh one thousand pounds, and dropped their first calf when they were 16 months old. I do not think the size or weight has anything to do with the profits in the dairy, for after a cow acquires the weight of from eight to ten hundred pounds, it is a burden to her, and what she will sell for after she is of no use in the dairy, amounts to naught.



I am not prejudiced against the Guernsey, but I know the Jerseys will return a good profit, both in milk and butter, and are the ones for us farmers of small means to keep.

To express my mind, a man might as well try to cut and bind a field of wheat with a mowing machine as to make a profit keeping dual-purpose cows; he will make about as much muss with one as the other.

Feasterville, Pa. W. H. W.

We take no particular exception to what our friend *says* in the above communication. He is about right as far as he goes, but like all the rest of us he has something yet to learn. Wider experience would have taught him, as it has taught others, that the dairy form is not wholly dependent upon Guernsey or Jersey blood, and, although not so mentioned, his present experience has probably convinced him that there are both Guernseys and Jerseys that do not have the dairy form or dairy ability; that, notwithstanding their imperial lineage, they are in effect "scrubs" and all the more dangerous because of the fact that they trace to distinguished ancestors.

Does it follow that HOARD'S DAIRYMAN is opposed to distinguished ancestors, and would ignore both breed and pedigree in selecting a sire to head either a distinctively dairy herd or a breeding herd? By no manner of means! No one has been more insistent than we that the dairy farmer should use pure-bred sires, and among them, only those that could trace to performing dams

BUHL CHEESE FACTORY CANS

Excel in Strength, Finish and Durability.

They will not leak or rust, are easy to clean, and keep the milk fresh and pure. The body sheets are the finest imported Cookley K Tinned Steel.

CAPACITY: 15, 20, 30, 40 and 50 Gallons.

AVOID IMITATIONS—All Genuine Buhl Railroad and Factory Cans are stamped with the Milk Can Trademark.

Write for our Handbook, "A Study in Milk Cans."

J. P. BRADBURY, . Pomeroy, Ohio.

and sires, not too far removed. But we go further than this, and because we do, the breed organs scold and fume like London fish wives. We insist, not only that the dairy sire shall be well bred, but that he shall show this in his form; show that he has inherited the qualities which made his ancestors famous; exhibit something more than a mere paper title to excellence. Many times we are compelled to buy and sell without other evidence of merit, than a charted pedigree, and because more frequently than otherwise, like produces like, we are not likely to disappoint or be disappointed.

But excellence sometimes crops out in unexpected places. American history is rich in the names and deeds of heroes and statesmen whose ancestors were not renowned and never had their names registered in congressional directories, or other official publications. So there are cows and families in all the dairy breeds, whose latent powers have never been developed, or if developed, never advertised. Advanced registries and books of butter tests are frequently receiving accessions from such sources, and it should no more occasion surprise to have a prepotent bull from such ancestry, than to have extra cows. But in either case it will be found the rule, to which the exceptions will be few and far between, that the dairy form accompanies performance. And the dairyman who is raising calves for the profit they will bring him as cows might better use a bull of proper form with an unfashionable pedigree, than one faulty in form no matter how gilt-edged his pedigree.

In its last analysis, breed is only another name for pedigree. There are breeds within breeds, only we call them families, and it is no more unreasonable to insist that great excellence can be found only in special families of Jerseys, than it is to claim that all great dairy excellence is confined to the Jersey breed. When it comes to individual excellence, type is more important than breed or pedigree. Mr. Hunter Nicholson in the *Jersey Bulletin* to the contrary notwithstanding.

Our Special Elgin Letter.

ED HOARD'S DAIRYMAN:—The offering of butter aggregated 15,960 pounds. A bid of 15 cents was made for the entire offering, but manufacturers refused to sell and the call closed with no sales made. The Quotation Committee announced the market steady at 17 cents.

The sales for the corresponding week of the three preceding years were as follows:

April 25, '98, no sales, market price, 16½ cents.
April 25, '97, 24,540 lbs. of butter sold at 16 cents.
April 25, '96, 43,320 lbs. of butter sold at 14@15c.

The New York market Monday was reported steady at 17 cents. Boston steady at 18 cents, and Washington steady at 19 cents.

Elgin, Ill, April 24. H. C. B.

Farmers' National Congress.

ED. HOARD'S DAIRYMAN:—The next session of the Farmers' National Congress will meet at Boston, Massachusetts, October 3rd, 4th, 5th and 6th. Section 2 of the constitution of the Farmers' National Congress determines the membership and reads as follows:

SEC. 2. The voting membership of this Congress shall be as follows: A member from each congressional district and two at large, to be appointed by the governor of each state (and such governors are requested to appoint practical farmers as such delegates); each Agricultural College and Experiment station shall be entitled to a delegate; and each national and state society or organization, created and maintained for the fostering of any agricultural interest in the western continent, shall be entitled to a delegate. These organizations, societies, etc., shall supply a certified statement of the existence of said organization.

Will you please give this communication a place in your columns, which we know are read by the officers of many of the organizations entitled to representation in the Congress. It is hoped that if this meets their eye, they will take the proper steps to have delegates appointed to the next annual meeting of the Congress.

W. D. HOARD, President.
Fort Atkinson, Wis.
JOHN M. STAHL, Secretary.
4328 Langley Ave., Chicago, Ill.

DAIRY MARKETS.

ELGIN, Ill., April 24—Butter—266 tubs offered at 15c, but no sales. Committee reported steady at 17 cents.

CHICAGO, Ill., April 24—Butter—Creamery extras, 16c; firsts, creameries, 14@15c; seconds, 13@13½c; dairies, selections, 14c; extra ladles, 12½c.

Eggs—Fresh, at mark, cases included, sold at 12¾c.

Cheese—Full cream, Twins, new, good to choice, 10½@11c; Young Americas, 11½@12c; Swiss, 10½@12½c; Limburger, 8½@10c; Bricks, new, 10c.

Bran—Scarce and quotable at $11.75@12 per ton.

Cattle—Receipts were estimated at 18,000, against 14,900 a week ago, and 11,108 a year ago. Our receipts were as large as the combined receipts at Chicago, Kansas City, Omaha, and St. Louis on the corresponding day last year. The general quality was good, yet with a scarcity of strictly prime beeves. Fancy cattle would sell around $5.80. Three head of 1,676 lb steers sold at $5.60, with $5.45 the next highest for a load averaging 1,421 lbs. Native steers ruled steady to 10c lower, with the decline mostly on heavy grades. Light beef cattle were fully steady, and native cows and heifers were without quotable change. Most of the native steers sold at $4.60@5; cows principally at $3.15@3.70, and heifers largely at $4@4.50. Feeding cattle steady, with sales at $3 90@4.25. Five loads of straight Texas sold at $4.35 for steers, and $3 35@3.75 for bulls and oxen.

MILWAUKEE, Wis, April 24—Butter—Creamery, fancy prints, per lb. 17c; Extras, per lb., 17@17½c; firsts, per lb., 15@16c; seconds, per lb., 14@15c; imitation, per lb., 14@15c. Dairy selections, per lb,, 13@14c; Roll, fair to choice fresh, 11@11½c. Market dull but steady, with continued accumulation of supplies, buyers taking only small lots, while receipts are 8,770 lbs

Cheese—American full cream, October Twins, 11½@12½c: new per lb., 10@11½c; Brick, new per lb., 10@10½c; Limburger, fall choice per lb., 9@10c; winter made, per lb , 8@9c; Swiss, drum, choice 12½@13c; Block, choice, 10½@11c. Market dull and quiet, trade being limited, with receipts 1,350 lbs and 11 boxes.

Eggs—Fresh, per doz., 12. Market steadier. Trade fair, chiefly for storing and receipts are 628 cases.

FOND DU LAC, Wis , April 24—Offerings 225 Twins and 250 Daisies; market active at 10½c.

AVOCA, Wis., April 24—Lone Rock and Muscoda Dairy Board held its first meeting to-day John Galagher was elected President; John McVey, Vice-President; Joseph Frost, Secretary and Treasurer. Offerings 308 boxes; market firm; all sold at 10½c.

SHEBOYGAN FALLS, April 23.—There were 347 boxes of cheese offered on the "call board" to-day and all but 10 cases of Longhorns were sold as follows: 145 Twins at 11c, 75 cases Young Americas at 10⅝c and 11c and 117 at 10¾c.

PLYMOUTH, Wis , April 18—On today's board 370 boxes of Twins were sold at 11¼c, and 60 boxes of Young Americas at 10¾c.

SHEBOYGAN, Wis., April 19—The sales on the call board today were 145 Twins at 11 cents, 75 cases Young Americas at 10⅝ cents, and 117 at 10¼ cents.

NEW YORK, April 24.—Butter—Creamery, Western extras 17c; firsts 16@16½c; state extras 16@17c; choice 16@16½.

Cheese—State full cream, large colored or white fancy 12@12¼c; choice 11½@11¾c; small fancy 12¾@13c.

Eggs—State, Pennsylvania and Western 14c.

BALTIMORE, Md., April 24.—Butter—Market easy; creamery separator extra 21@22c; extra first 20c; creamery first 19c; ladle extra, 14@15c; Western store packed 11@13c.

Eggs—Market firm; strictly fresh stock 13c.

PHILADELPHIA, Pa., April 24.—Butter—Solid packed separator creamery, extra, 18c; creamery firsts 17c; seconds 16c; imitation creamery, extra 16c; firsts 15c; seconds 14c; ladle packed, extra 15c; firsts 14c; seconds 13c; print butter, creamery, extra 20c; firsts 19c; seconds 18c.

Eggs—Pennsylvania and near-by 13c; Western 13@13½c; Southwestern 13@13½c; Southern 12½c.

BOSTON, April 24—Butter—Creamery extra, 18@18¼c, western extra 18@18¾c; dairy extra 16¾@17c; imitation creamery 15c; western ladle 14c; print creamery 19c; box creamery 19c.

Eggs—Fancy near-by 16@17c; choice fresh 14½c; Michigan extra 14@14½c; western 14c; fair to good 13½@14c.

ST. LOUIS, Mo., April 24.—Butter—Steady; creamery 15@20c; dairy 13@17c.

Eggs—Lower at 11c.

KANSAS CITY, Mo., April 24.—Butter—steady; creamery 14@19c; dairy 15c.

Eggs—Demand light; weaker feeling prevailed to-day, though prices remained unchanged; fresh Missouri and Kansas stock in new cases, cases included 12c; cases returned 11½c.

NEWARK, N. J., April 24.—Market steady 17c for best western extras. Receipts liberal.

WASHINGTON, D.C., April 24.—Market steady, extras 19½c; firsts 18c.

CINCINNATI, Ohio, April 24—Market weak; Elgin 60 lb tubs 19½c; prints 20½c.

NEW ORLEANS, La., April 24.—Market weak. Free offerings 18@19c.

Latest quotations for fancy creamery:—St Paul 17c, Minneapolis 17c.

NEW YORK MARKET.

NEW YORK, April 22—Butter—Receipts for the week, 37,755 packages. Exports for the week, 355 packages.

There was plenty of fresh creamery butter this week, and although trade is very good, prices declined one cent per pound and our market closes with some stock being carried over, and prices in buyers favor. The quality of butter is not as good as it ought to be, and a large proportion of the western creameries were turned down this week by buyers who have used them all through the season. Exporters are looking for fresh ladle butter, and would pay 14½@15 cents for finest, but this style of butter is very scarce; at the close this trade is reported to have bought several lots of finest creamery at 17 cents. We quote: Creamery, extra, 18c; medium, 16@17c; poor, 14@15c; Dairy, extra, 17c; medium, 15½@16½c; poor, 14@15c.

Cheese—Receipts for the week, 8,209 boxes. Exports for the week, 2,826 boxes.

Little doing in old cheese and prices easier on all grades. The receipts of new are increasing, and we note sales for export of large cheese at 9@10c, and small sizes to local trade at 10@10½c.

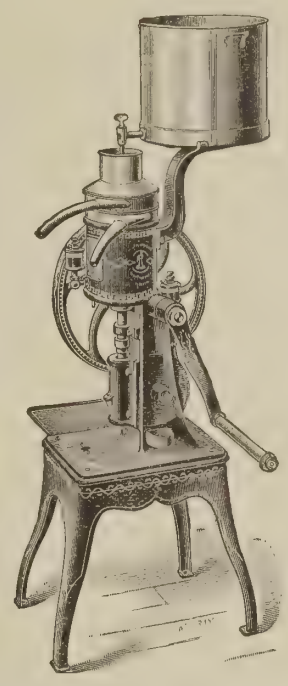
All kinds of poor to good quality new cheese sell slowly at very irregular prices. We quote: Full cream, old, extra, 11@11½c; medium, 9@10c; poor, 6@8c; Full cream, new, extra, 10@10½c; medium, 8@9c; poor, 5@6c.

Eggs—Receipts for the week, 57,808 cases. Quite a falling off in demand, and prices are about 1c dozen lower than last week. We quote: New York & Pennsylvania, per dozen, 14@14½c; Western & Northern, 13⅝@14c per dozen; Southern, 12@13c per dozen. DAVID W. LEWIS & Co. 177 Chambers St.

FOREIGN MARKET.

BOSTON, April 22 Butter—Cable advices of this date, from the principal markets of Great Britain to G. A. Cochrane, give butter markets as dull and declining. While stocks are not burdensome, and receipts only moderate; buyers are very conservative in anticipation of increased receipts of Irish and Continental. Australian butters are now in very small compass and will soon be out of the way, values of which are nominally 20@20½c. Arrivals of Canadian are light and when in boxes sells at 20@21c, for finest. American butter is meeting with a poor demand; stocks however, are not large, and there is little or none left of creameries good enough to command over 18@18½c. Some fine imitations are selling at 16@17c. Ladles are moving out slowly, and free sales cannot be made except at 15c downwards. Fresh Danish and Irish are the most popular butters at the moment. Finest Danish takes a range of 22@23c, with very fine Irish offerings at 21@22c, but prices from now on will rapidly decline.

Cheese—Markets, while steady, and with finest descriptions of Canadian firmly held, there is little prospect of any improvement on present prices, which are 11½@12c. Anything under finest is very scarce and in active request.



MANCHESTER, England: Dowdall Brothers' special report of April 8th, says: Copenhagen market weaker, with plenty of butter offered at reduced prices. It is expected that official prices will be reduced 4 kroner, and as exporting is likely to give losses, holders prefer realizing here at a sacrifice whenever possible.

Manchester had a fairly brisk market, and cleared extremely well in the face of the cautiousness of buyers and of the Easter holidays. There was a slight reduction in price. Rates here have been well maintained, owing to recent wild and stormy weather, the decrease in Colonial supplies and the lateness of the season in Ireland. Irish is beginning to make its appearance, and at reasonable prices, with good quality. Manchester received 1,020 Finns or 147 more than the previous week. For next week's North of England markets there are advised 20,437 casks of Danish and Swedish, or 437 casks more than last week, and 2,969 casks Finnish, or 391 more. Margarine arrivals through Hull, 11,416 packages, and via Grimsby 5,710 packages.

LIVERPOOL, April 24.—Butter—Finest United States 84s; good 65s.

Cheese—American finest white and colored 52s 6d.

Buttermaker is wanted at Pine Grove Creamery. Address immediately, giving references as to character and ability. S. E. RIGG, Valparaiso, Ind.

A Good Bargain—For Sale, the young Jersey bull Tom Goldfinch 52166. Sire, Cambronne 40614. Dam, Lady Goldfinch 72214. Dropped Oct. 8, 1897. Grandson of Grand Khedive 30474. Is a fine animal with splendid blood lines. Will be sold cheap. Address F. A. TILDEN, Fort Atkinson, Wis. 11-2

Wanted—A single man to work on dairy and stock farm. Must be a good milker. Board and washing furnished. State wages and give reference. Address J. L. ROBERTS, Foreman, Saxony, Ind. 11-2

For Sale—Five Holstein-Friesian Bulls ten and twelve months old. Also B. Plymouth Rock eggs for hatching, Address C. W. SCHERMERHORN, Charles City, Iowa. 11-4

$75.00 will buy registered bull Gerben Mechthilde Sir Josephine 2d, H. F. H. B., born August 28, 1897. Reason for selling, compelled to give up dairying. C. KAHLER, Prairie au Chien, Wis. 11-4

For Sale—Fifteen h p. boiler and 15 h. p upright high speed engine nearly new, also 6 h. p. engine. GEO. WOODRUFF, Adm'r, Janesville, Wis. 10-3

Haunts in the Wild Woods and gay places for summer outings. Either or both, can be found along the lines of the Chicago Milwaukee & St. Paul R'y in Wisconsin, Minnesota, Northern Michigan, Iowa and the Dakotas. Among the many delightful summer resorts are Delavan, Waukesha, Oconomowoc, Elkhart Lake, Marquette, Madison, Kilbourn, Minocqua, Star Lake, Lakes Okoboji, Spirit Lake, Clear Lake, Big Stone, Frontenac, White Bear and Lake Minnetonka. In the north woods of Wisconsin, in the forests of Northern Michigan and Minnesota, and in the far stretches of the Dakotas true sportsmen can fish and hunt to thier heart's content. For pamphlet of "Summer Tours," and "Fishing and Hunting," apply to nearest ticket agent, or address with two cent stamp, GEO. H. HEAFFORD, Gen'l Pass, A't., 535 Old Colony Building, Chicago. Ill. 9-3

For Sale—Holstein-Friesian bull calves of choice breeding. Will sell cheap if taken soon. For particulars address, JOHN SHUGART & SON, National Military Home, Ind. 7-6

"In Old Kentucky."

The Soja Bean Problem.

ED. HOARD'S DAIRYMAN:—Only a few of us down here in old Kentucky have as yet engaged in the dairy business. It is generally considered a little business here and becoming only to the person who mounts the "critter" on Saturday afternoon and with 4 pounds of butter in one end of a basket and 3 dozen eggs in the other goes to the country store to exchange its value, which is $.67, for goods. This $.67 generally represents the week's output of produce from the farm, and if invested, as it generally is, say 5c in soap, 10c in oat meal, the same amount in starch, and some in soda, and perhaps a package or two of coffee, the farmer is all smiles and heard to exclaim, "this produce mounts up in the cose uv a year; I need a 'nuther' basket to take home what my 'marketin' brought; hit helps out mightly", etc.

Then he is off perhaps for the saloon for a "good send off", and returning to the grocery store takes a chew of "homespun" and is therewith content the balance of the afternoon "postin" himself in national affairs, or rather posting everyone else. He understands the financial question perfectly and takes his party paper, but ask him what agricultural literature he reads, or better still, talk to him about 5 minutes about stock feeding, balanced rations, economical production of beef, pork or butter, or the restoration of tired lands, and ask him what he would do and why he would do it, etc., and his answers will explain to you why he places so low an estimate on the dairy.

What do dairymen think when I say that there are many farms, of 300 acres, say, in this county with a total gross income of less than $700 per year, and the gross receipts a little less every year, with a corresponding decrease in the value of the farm. The making and applying of manure is the work most neglected of all. These same farms occupied by intelligent dairymen would in 5 years easily increase this gross income to $1,800 or $2,000 per year, while the value of the farm would be increased certainly not less than 6%. Years may come and years may go but it looks as if this poor shiftless way of farming in Kentucky is to go on forever.

But I am about to forget the object of this communication, which is to make some inquiry about soja beans. I want to grow protein, so to speak, and in addition to clover I will use cow peas pretty extensively, and have already bought 10 bushels of soja beans. I believe analysis puts them above peas, but want to hear from the editor and also from practical dairymen, who have been growing them for cows, and also for hogs, and as a soil renovator. How do they compare with southern peas as food for stock? How as a restorer of tired land? Shall I plant in rows and cultivate, or is it better to drill or broadcast them? I should like to know its value as ensilage. A friend of mine put about 30 tons in silo last year and is much pleased with it. Please turn on the light and oblige. P. W. F.

Irvington, Ky.

All persons interested in soja (soy) beans should send to the Secretary of Agriculture, Washington, D. C., for a copy of Farmers' Bulletin No. 58, which treats of "The Soy Bean as a Forage Crop." Meantime we copy from this bulletin as follows:

In a general way, the same methods of culture may be recommended for the soy bean as would be given to the ordinary field beans. The soil should be well prepared, so as to afford a good root bed, and should be left smooth and free from clods in order to facilitate the cultivation and harvesting of the crop.

Although soy beans may be planted quite early in the season, the best results will be obtained if the seeding is postponed until the ground has become thoroughly warm; and in case the earlier varieties are used, a fairly good crop of forage or even of seed may be obtained, if the seeds are not planted until the earlier small grains, such as rye and barley, have been harvested.

Another practice is to drill the beans in between the rows of corn after the last plowing; they are also sometimes planted between the hills of corn, as are field beans. The best method of seeding will depend somewhat upon the kind of crop which it is desired to harvest. If the soil is good, and a crop of hay or green fodder is desired, good results may be obtained by sowing broadcast or with a grain drill. If, however, a crop of beans is desired, it is best to plant in drills from 2 to 3 feet apart, according as the soil is light or heavy.

There is considerable difference in the amount of seed sown per acre in the various parts of the country; some farmers sow only about half a bushel per acre, while others prefer a bushel or even more. The proper amount will necessarily vary somewhat, according to the method of seeding and the character of the soil. As a rule, when grown for seed, from one-half to three-fourths of a bushel per acre will be ample. When put in with a grain drill or sown broadcast, a greater amount of seed will be required; but in any case it will hardly be necessary to use more than 1 bushel per acre. Of course, less seed will be required when the grain drill is used than when the seed is sown broadcast, and as a rule better results will be obtained. When planted for beans, enough seed should be used to give an average of five or six plants per foot in the row. If nothing better is at hand for planting the seed, an ordinary grain drill, with enough of the holes stopped up to give the desired distance for the rows, may be used. For example, if the holes are 8 inches apart, number 1 may be left open, numbers 2, 3 and 4 closed, number 5 open, etc., and the rows will be 32 inches apart, or, if a less distance is desired, number 4 may be left open and number 5 closed, and the rows will be 24 inches apart. In very light soil the latter distance would probably be best, but in heavier soils the former would be preferable.

When the seed has been drilled in rows close together, or has been sown broadcast, very little cultivation will be necessary. It will sometimes be found advisable, however, to cultivate the drilled field soon after planting, as in case the land is very foul, the weeds are liable to get such a start that they will interfere with the growth of the young soy plants. For this purpose use a light harrow. When grown for seed, thorough cultivation should be given, at least while the plants are young. As a rule, cultivation should be shallow and frequent if the best results are to be obtained. When the ground is inclined to pack or bake, it should be stirred after each rain, but care should be taken not to work the field when the plants are very wet from rain or dew. If the drills have not been made too far apart, it will be found that the plants will soon shade the soil sufficiently to keep the weeds in check and to keep the surface in good condition, so that much cultivation will be unnecessary. In fact, on good soil very fine crops have been obtained with but a single stirring of the soil after the seed had been planted. As a rule, this crop will require a smaller amount of cultivation than corn.

Silage as a Producer of Healthy Milk.—Alcohol in Silage.

ED. HOARD'S DAIRYMAN:—The following inquiry has been received: "Letters which we receive from time to time, indicate that there is a very decided inclination among Boards of Health and doctors acting as health officers to decry the use of ensilage as a milk producer.

Among other things they bring up the action of alcohol assumed to be in silage and the abnormal composition of casein, brought about by the use of the above feed. Owing to the almost universal ignorance of doctors on the subject of animal feeding, the use of silage is being prohibited in many localities, on these grounds. Could you not supply some data on the above points?"

Objection has at times been made on part of milk-condensing factories to the use of silage as a feed for milch cows on account of the supposed injurious effect of the silage on the flavor of the milk, and perhaps on its keeping quality. The prejudice against silage in some quarters is doubtless traceable to careless feeding of sour silage made from very immature corn. One can overdo everything; a fair allowance of silage being a good thing, it does not follow that a cow can be advantageously fed on silage as sole roughage. It is generally not advisable to feed more than 40 to 50 pounds of silage, per cow, per day, giving all the dry fodder or hay she wants to eat, in addition to the grain feed. Fed in this manner there can be no objection whatever to the use of silage for milch cows; in fact, there is no feed that can be fed more economically under our conditions and with better results as regards the quality of the product obtained. That not all condensed milk factories are averse to the use of silage by their patrons, is evinced by the fact mentioned in Prof. Henry's Feeds and Feeding, that the Michigan Condensed Milk Co. with factories at Lansing and Howell, Mich., accepts milk from silage-fed cows and urges its patrons to build and use silos; the only condition set being that nothing but well-matured corn be used.

There is no evidence that silage fed as suggested will bring about an abnormal composition of the casein (I suppose the term is meant to include the nitrogenous components of the milk) and no reason is apparent why it should have any such effect. The silo is getting to be more of a necessity to the American dairy farmer with every year that passes, no matter whether milk, cream, butter, cheese or condensed milk is the final product sold, and if any abnormal changes were apt to be worked in the composition of the milk from its use it would have been discovered long before this.

The alcohol found in silage can in no way influence the quality of the milk. There is not enough alcohol in the silage to be determined quantitively by the most delicate chemical methods; it is indeed often difficult even to show that it is there. I have but rarely failed to find alcohol in silage when I have looked for it, but it is necessary to use the microscope to decide whether the characteristic reaction showing the presence of alcohol has been obtained. There is therefore only an infinitessimal quantity of alcohol in silage, perhaps not more than is found in bread, which for some time past has been considered "the staff of life" and very likely will continue to be so considered, in spite of the fact that minute qualities of alcohol generated in the fermenting (working) of the dough remain in the bread after it is baked.

The objections to silage as a feed for dairy cows are therefore wholly unwarranted, and no company, doctor or Board of Health can prohibit its use, for this purpose, without thereby showing that they have not followed the progress of dairying and cattle-feeding in this country or abroad. The silo is as important an adjunct to modern dairying as is the separator or the factory system of butter and cheese making. F. W. WOLL.

Wisconsin Experiment Station.

Satisfactory Experience With Stave Silo in Kentucky.

Various Queries.

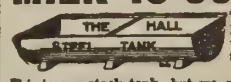
ED. HOARD'S DAIRYMAN:—Last fall I built a tub silo according to your plan with sketch given in one of last year's copies. I have just finished feeding, and it has kept well to the bottom, excepting around edges, probably from lack of tramping. My experience, however, is that I must have a good roof over it. Last fall was very wet here, and I think some spoiled on top because of leaky roof. A bad roof is certainly worse than none, as with no roof the rain will be evenly distributed, while a leaky roof will make seeps, penetrating deeply.

I think I saw where some one covered the full silo with saw dust; this is plenty and cheap here, and could be carried up with elevator. Do you think it would injure the silage?

I also had trouble with the uprights through which the iron rods pass, they bulged the silo walls on the inside where they lay, causing the rods to draw the tub out of round. Now that it is empty, I have put cross bracing in, before tightening, to remove before filling.

I want to build another one this fall, on this plan. I think it is good enough for me; if there is a better way to do this, I would be glad to learn it.

My roof is simply boards, covered with tar paper, no rafters. I simply nailed small strips underneath to hold boards as one; gables nailed up from tub to roof. There was plenty high wind to test it this spring. I have only two holes in 20-ft. tub.



I have often had my oats damaged by wet weather and big binder bundles. Can bundles be made smaller some way? How would it do to make ensilage out of it, when nearly ripe?

How do you keep your large water tanks from freezing in winter (steel or wood) or rather from bursting?

Finally, my steam gauges, both on boiler and separator, stop on 5, when cold. They were frozen this winter; how does it affect the proper reading?

I live in a poor dairy country here; people won't get out of their old ruts. I get about

20 cents for my butter and make a fair living by hard work and by working my boys, in place of sending them to school. Public schools are very poor here. I teach them at home.

I make this a pretty long letter, but I just want to show you that I appreciate HOARD'S DAIRYMAN, and then I won't write you so soon again.

I have been grinding corn in iron mill, and also in crusher this winter. I was painstaking not to get any iron in corn, but a nail or a small bolt turned up now and then, so it will take a new set of burrs every winter. I see that millers use magnets to catch them. Would they be effective on an iron mill?

Bardstown Junction, Ky. C. H.

Communications like the above, filled with a record of facts, drawn from experience, are full of instruction.

Sawdust makes excellent covering for silage. The point is simply to exclude the air. Anything that will accomplish this answers the purpose. Whether to use sawdust, swale grass, paper and boards, chaff or other material, depends solely upon cost and convenience. When the sawdust is evenly distributed over the surface, it would be an excellent plan to wet it down thoroughly as this will make it more impervious to air.

The pressing in of the staves was caused by the hoops becoming too tight in consequence of the swelling of the staves. If the nuts on the ends of the hoops had been loosened a little on the first appearance of inward pressure of the staves, the difficulty described above would have been obviated.

In building new silos this year, we suggest to C. H. that he study the description of the silo built at Purdue University, which was given in the last issue. Instead of using separate blocks, pieces of 4x6 were used in place of two of the staves, holes being bored at proper intervals through which to run the ends of the hoops. However, the use of these pieces in place of the staves will not obviate the necessity of keeping pretty close watch to see that the hoops are not drawing too tight.

All the self binders with which we are acquainted, make provision for increasing or decreasing the size of the bundles to be delivered. Unless the agent, from whom this machine was purchased, can give specific instructions for working this device, we advise our correspondent to write to the manufacturer of the machine, and they will very promptly give him detailed instructions what to do. Oats do not make first-class silage, largely because such silage does not keep well. The hollow straw permits too much air to remain in the silo, and thus furnishes conditions for inducing decay.

The only way known to us for protecting tanks is to cover them sufficiently to exclude the frost, leaving only a small opening for the cattle to drink from, or better yet, provide a short spout to lead from the large tank into a smaller one as may be necessary for watering the stock. In lieu of covering so much as completely to exclude frost, less covering may be used in connection with the tank heater.

We are not quite certain as to the reliability of the gauges referred to. It is just possible that they may be accurate by deducting 5 from the registered reading, but we should hardly like to rely upon such a conclusion. It would be much better to send away and borrow a gauge that is known to be accurate, and test those which are now out of condition.

We know of no reason why the magnets should not work as well in connection with an iron mill as with any other.

RAISING BEEF AT A LOSS.

Prof. Shaw argues that the dual purpose cow is a necessity because the range cannot grow enough beef for the country to eat, and to grow the remainder with special purpose beef cows on arable land is too expensive a process. Therefore some one must keep dual purpose cows and milk them, and also raise steer calves from them. This is a good argument.—*Republican*, Waverly, Ia.

To our mind this is equivalent to saying that the range cannot grow beef enough for the country; therefore somebody must keep beef cows for dairy purposes, be to all the extra expense which the dairy involves, including extra care, feeding, transporting the milk to the creamery, etc., and in the end lose money on such cows in order to raise steer calves from them. Is it not time to admit in this argument, that the real logic of the case lies in the fact that if men become dairymen, they must subject themselves to the same expense in fixed charges with a poor cow, a scrub cow, a half way cow,—dual-purpose—that they would with the best sort of a dairy cow? That when once they embark on this road of dairying, the natural logic of trying to secure the best return for their capital, labor and expense, should lead them to secure the best paying cow machine they can?

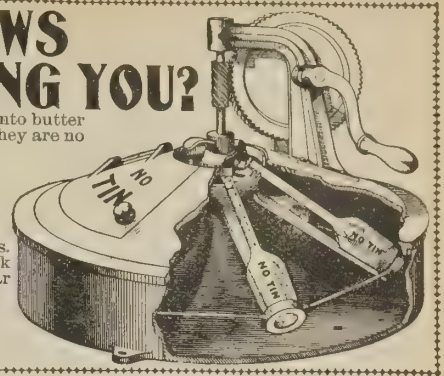
Every farmer in the land, who is contenting himself with cows that just about pay for the food they consume, or maybe lose money for him, is an advocate of general-purpose breeding and general purpose management.

A large proportion of these men have never put pencil to paper to figure the expense of keeping a cow, or what a cow should yield to afford a fair revenue. On the general purpose side of the question is found the vast host of farmers who have no ambition or care to be well posted dairymen, and thus secure the larger revenue that comes from special-purpose ideas and cows.

Everywhere through the land wherever we find a man with true dairy ideas, we find him with cows posessing more or less special-purpose blood.

Special-purpose ideas in the dairy business lead naturally to improvement in dairy cattle, breeding in more and more of dairy capacity, and a general grading up of the man himself. Dual-purpose ideas lead where the thousands upon thousands of farmers with poor, unprofitable cows find themselves to-day.

ARE YOUR COWS CHEATING YOU?



Are your cows turning the feed they eat into butter fat, or are they just living off of it. If they are no good they should go to the butcher.

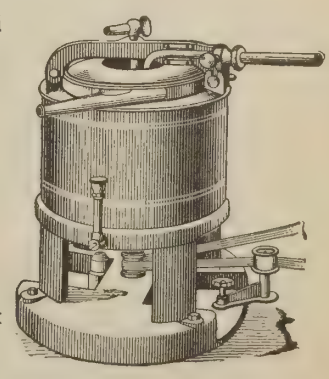
Is Pasteurizing A Success?

Ask the creamerymen who are making pasteurized butter and the butter men and retail dealers who are selling it. Ask them how it compares with other butter—if it doesn't command better prices—if it isn't preferred by consumers. Read what Philadelphia's largest commission merchant says about the rapidly growing demand for pasteurized butter:



PHILADELPHIA, March 1, 1899.

Dear Sir:—In reply to your inquiry regarding the merits of pasteurized butter, would say that we are receiving it from a number of creameries who have adopted your system of pasteurization, and the only difficulty we find is, we are unable to supply the demand. Pasteurized butter makes its own way in the market and commands a far better price than the average good creamery butter. We are always ready to pay a good price for pasteurized butter and buy as much of it as we can get.

Water and Market Sts., Philadelphia. JOHN JAMISON.

A Milkman's Queries.

An Ohio reader is considering a proposition to establish a milk route in a manufacturing city in Ohio of about 6,000 inhabitants and submits the following queries:

How can we best build up a trade for bottled milk to be sold at 6c per quart and 10c per pint for cream? There are many wagons in the town now drawing milk from the can at 5c per quart. We expect to run the milk from a separator, cool and bottle. Would it be best to remove enough of the skim milk so that we could guarantee the remainder to contain 5% fat.

Please give method of sterilizing bottles and required apparatus for the job.

What thickness of cream is it best to run through a separator? To what temperature should the milk be cooled? Would you recommend the Star cooler? Would you run skim milk and cream together after leaving the separater and then to the cooler? Would not bottled milk put in sterilized bottles and cooled to from 40 to 45° keep to 36 or 48 hours in a temperature not above 70°?

Our plan is to use a turbine separator of 300 to 600 lbs. capacity per hour. What size boiler would be required or would be best?

Would like to have a plan for dairy house, with ice for the refrigerator. What is the best material for floor? Is it best to have ice-house separate from the other buildings? Can a dairy house be built for $40, having a herd of 30 to 40 cows?

Would it be a good plan to make a stave silo of two-inch pine, 20 ft. long, and paint the edges and inside before putting it up? What kind of paint is best, what kind of root? Could we hoop the silo with heavy galvanized wire? Any other suggestions would be thankfully received. P. B., Jr.

Gratiot, Ohio.

There are many ways of building up a milk route. One of the most successful milk routes in Boston was established without advertising or soliciting of any kind. The proprietor started in moderately, was resolved to serve his customers at all times and under all circumstances with strictly pure, clean, high-class milk. Doing this, his customers became his advertisers, and their friends called in the distributors from time to time, until the business has grown to wonderful proportions. It does not follow that a similar course would be equally successful elsewhere. Personally, we believe in the efficacy of advertising. If a man has something to sell or wants to buy something, we know of no so sure a way of making his wants known, as judicious advertising; and, as a rule, this is best done in first-class papers circulating among the people to be reached.

In the milk business, in particular, performance must keep, at least, equal pace with promise. Doubtless the distribution of free samples, accompanied with a guarantee that the regular product shall at all times be equal to the sample, might prove advantageous. In order to accomplish this with certainty, it is necessary to use the separator, and remove enough of the skim milk to insure the regular and the promised proportions of fat. It is not at all certain that it is necessary to have this as high as 5%. Not a few families would probably prefer 4% milk at a proper reduction in price. If there are others who desire a richer milk, or one approximating cream in richness, be prepared to comply with their demands. There is no more reason why every family in the city should be obliged to purchase milk of uniform quality, than that they should purchase coffee and tea, and other groceries of the same quality.

There are various ways of sterilizing milk bottles and other milk utensils. In a small way this is best accomplished by the use of boiling hot water. Where there are a large number of bottles to be sterilized, some special apparatus for using live steam, would be more convenient. Various devices are manufactured for this purpose, and we advise the inquirer to address the different manufacturers on this subject. Any of the firms advertising dairy supplies in HOARD'S DAIRYMAN, will answer such inquiries promptly.

The ordinary standard for commercial cream is from 22 to 25 per cent fat. It was formerly considered indispensable to cool the cream down as low as possible, and we still believe this is the most practicable way, at least for the retail milkman, but we read there are large shippers of cream who start their consignments on long railway journeys, heated up to 150°. This, of course, implies that the cream has been pasteurized. There are various forms of coolers on the market. The one mentioned by our correspondent has a good reputation, but in this, as in all other matters of similar nature, we cannot be expected to pronounce upon the relative merits of rival machines or implements.

After running milk through the separator, the skim milk and the cream should be reunited before being cooled. We think it very doubtful whether milk put in sterilized bottles and cooled to 40°, would thereafter keep for the length of time mentioned in a temperature as high as 70°.

When one purchases a separator, or any other machine, he should confer with the parties selling the same and get their advice as to the character and amount of power required.

We have already published, in a recent number, a plan for a farm creamery, including a refrigerator. Where only a milk and cream business is done, possibly the size might be reduced, otherwise we cannot suggest any desirable change.

The stave silo question has been pretty thoroughly discussed elsewhere in this issue and in several others that have preceded it. There is no objection to painting the inside and edges of the staves with coal tar, provided that the lumber is perfectly seasoned.

Heavy galvanized wire would not, in our judgment, suffice for hoops. Some method must be resorted to for tightening and loosening the hoops on a stave silo. This could not be done by driving hoops up or down, as one would on an ordinary barrel, for the reason that the silo is the same size from the top to the bottom.

A Dairyman's Adversity.

Losses From Abortion and Garget.

ED. HOARD'S DAIRYMAN:—I know a young man who began dairying several years ago, and has not prospered for reasons apparently beyond his control. He has worked hard for success, he has practiced the best methods of dairy farming, as far as he was able. When he came in possession of his farm, the first thing he did was to try to improve his cows. With his farm he got a dairy of very poor cows, and he began at once to improve his herd, by using a thorough bred bull. By raising the calves from his best cows, he was able, in a few years, to build up a fine herd of grade Holsteins.

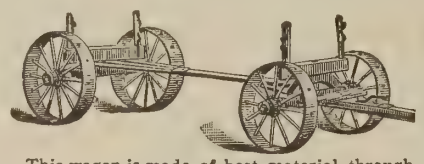
In the meantime he had built a silo, and repaired his buildings. By making and saving more manure, he made his farm more productive, so he was able to keep more stock.

After he had worked so hard, for several years, to bring about these improvements in his farming, and when the future looked bright to him, for he thought he would now obtain some of the results that would come to him from his work, he began to have trouble with his cows.

There is nothing else a dairyman fears so much as disease among his cows, especially if it is one he cannot control. This fine herd of cows that had cost their owner so much work was made almost worthless by abortion; the disease was so contagious that for two or three years in succession, the most of the cows aborted. The young man was in debt, and receiving but little income from his dairy and this time he was unable to make his expenses.

He finally got rid of the most of the cows that had aborted, and raised or bought cows to take their place. When he was recovering from his losses from abortion, and was making some money from winter dairying, he began to have trouble with the garget. With some of his best cows, the trouble was so severe, that the udders were so badly affected, as to make them worthless, and the cows had to be sold for beef.

He kept raising and buying cows to take the place of the cows that had proved worthless to him, and persevered until he got his cows on a paying basis again, and was in condition to make some money. Then followed the long drouths of '96 and '97, when in the eastern states, for two years in succession, the hay crop was almost a failure, and farmers had to buy grain to supplement their pastures, in the summer.

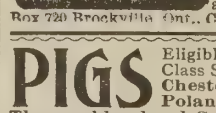


In these years, this man has seemingly done all in his power to make his farming a success; he has worked hard, and has been progressive in his dairy farming, but he is still in debt, and the lower prices of dairy products, of the present time, makes the debt more difficult to pay. Besides the adversities mentioned, he has suffered loss in the depreciation of farm property, and this shrinking has, in twenty years, been nearly one-third on real estate in the country. This instance I have described, I know, is somewhat exceptional. With usual conditions, the efforts of this man would have been rewarded with success, and it is only along the line that he worked, that dairying can be made profitable.

My reason for writing about this instance of adversity is, to ask what the veterinary science of to day can do to prevent or cure the diseases, which were the main cause of the losses suffered. I think if this man had asked the advice of the best veterinary authorities, that they would have been able to help him but little. They may be able to prevent, or cure many diseases, and by using their remedies, he probably could have avoided much trouble from the garget, but with the abortion there was no help for him, from medical science, that could arrest it so as to save him from great financial loss.

It certainly will be of great interest to the

Farm Wagon for Only $19.95.



In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, sold at the low price of $19 95 The wagon is only 25 inches high, fitted with 24 and 30 inch wheels with a 4 inch tire.

This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Co., Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

readers of HOARD'S DAIRYMAN to know just what our best veterinary men would do if they were placed in the circumstances I have described. No doubt the germ theory of abortion is the correct one, and it will afford the dairyman some satisfaction to know the cause of contagious abortion, and he is waiting for further researches that will enable him to prevent or cure it.

A SUCCSSFUL ENTERPRISE.

In my town there are two creameries. These creameries buy the milk of the farmers, and the greater part of the milk is bottled for a retail trade in New York City. A part of the milk is run through the separator, and the cream bottled for the city trade. These creameries own milk routes in the city, where they are able to retail milk and cream for the highest prices.

Much of this milk is sold for eight cents per quart, and the price paid the farmers in the summer, is but little more than one cent per quart. The farmers became so dissatisfied with the prices paid for their milk, that one year ago they organized a stock company, and contracted with the Elgin Creamery builders to build a creamery for making the Elgin creamery butter, to be managed by the farmers on the co-operative plan.

This creamery has been in operation for one year. An expert butter maker and his assistant are making the butter that commands the highest market price. The other two creameries have been nearly deserted by the farmers, and the butter factory is getting nearly all the milk made in its vicinity. The farmers find the butter factory is the most profitable, and seem to be well satisfied with their investment in creamery stock. The plan of the co-operative butter factory has much to commend itself to dairymen, but, of course, its success depends entirely on its management. W. J.

Delaware Co., N. Y.

Preliminary Feeding for Fattening Steers in Tennessee.

ED. HOARD'S DAIRYMAN:—A neighbor aims to feed 200 two year-olds next winter and fatten for beef in spring and summer. Says he will feed cotton seed hulls and cotton seed meal. I contend that he should feed some hay, at least, and corn and cob meal or corn meal as part of grain ration. Please give ration for same with following prices: Cotton seed meal $15, hulls $3 00@$4.00, corn 20 cents per bushel, corn and cob meal delivered $9, bran $12, pea hay $6@8. Don't think he will have any stover. Our Southern farmers save only corn blades. If clover hay can be imported for $6, would it be better, with pea hay at maximum price? Cows doing well "considerin.' "

Expect to put in Scott's stalls before another winter. Will get a separator in a few weeks and build a silo, perhaps on Mr. Van Norman's cheapest style. Have much greater margin of profit than most small dairies in the North, but want to improve anyhow.

Humboldt, Tenn. J. W.

Experiments at the South seem to have demonstrated that cotton seed meal and hulls make a fairly satisfactory ration for fattening steers. With a feeding period lasting from 100 to 125 days, it is usual to commence with three or four pounds of the meal, gradually increasing to eight and sometimes ten pounds per head daily. In addition they should have all the hulls they will eat, which will probably average from three to four pounds for each pound of meal.

It is our opinion that better results would follow if at least a portion of these hulls were mixed with the meal. Cotton seed meal is a very concentrated feed. By that we mean that it carries a large amount of nutriment in small bulk, and it seems reasonable to expect that if this meal is diluted or mixed with hulls or with wheat bran, digestion will be very much aided.

The foregoing is not a direct answer to the specific question, which was how to feed steers during winter preparatory to fattening them the following spring and summer. Of course, we cannot speak from experience with cotton seed meal and hulls, but the conclusions we draw from our reading are that an exclusive diet upon these articles is likely to beget more or less aversion. It would seem, therefore, much the better practice during the preliminary period to add something by way of variety. The suggestion as to hay and corn and cob meal is, therefore, a very good one, in our opinion.

It is hardly practicable to specify either the total or the proportionate amount which should be fed. This must be determined largely by circumstances as they arise from day to day with different animals. Some will take more and some will take less. The rule is to feed up to the limit that each will eat with relish. A variety in the ration stimulates appetite and this in turn aids digestion. One matter too frequently overlooked is a daily allowance of salt, or placing a supply where the animals can have access to it at will.

Cow pea hay carries more protein than common clover hay, and for milch cows is to be preferred, but where cotton seed meal is fed freely, which supplies all the protein that can be profitably used, we should prefer clover at $6.00 per ton to cow pea hay at $8.00 per ton; and if some of the native grasses, such as Bermuda, Crab, or Johnson, could be made into hay, we are not certain such hay would be inferior to clover.

Oat and Pea Hay.

ED. HOARD'S DAIRYMAN:—In reply to A. D, Marion, Indiana, page 151, have to say: I have grown oats and peas for hay a number of years, and do not think anything will come so near filling the place of nicely cured clover hay for milch cows, as nicely cured oat and pea hay.

When changing, in feeding from one to the other, do not notice any d fference in yield of milk. Peas should be sown as soon as the ground will do to work. I plowed in one acre yesterday afternoon, April 6th.

My mode of raising is as follows: Harrow the ground thoroughly, both ways, with disk harrow, then sow the peas, (Canadian) just as when sowing oats broadcast, three steps apart, two bushels to the acre, and plough them in four inches deep. In about one week, harrow the ground thoroughly both ways, with smoothing harrow, teeth straight, and drill in a stiff strawed oat, one bushel to the acre.

This year I will try using more oats, up to two bushels. Cut early and make the hay just as clover. If the peas get too ripe loss will result from shelling, and the hay will not be near as good.

The yield will depend on richness of ground and season. Last year my yield was not so good as the year previous, owing to a dry June. Next to peas and oats, I like Hungarian grass for hay. Last year I sowed the latter after taking off a crop of oats and peas, and had fair returns, owing to plenty of rain in July and August. J. R. H.

Dayton, Ohio.

Sweet Corn Profitable for Silage.

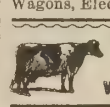
Experience of a Close Observer with it, and in other Matters Ancillary to Profitable Dairying.—Quantity of Milk as Important as Quality.

ED. HOARD'S DAIRYMAN:—I thank you very much for the full and satisfactory reply to my inquiry published in your issue of April 7, page 157; and concerning your comment on the quality of cotton seed meal, will say: It is the American Cotton Oil Co's product, and each sack has their "red tag" showing guaranteed analysis, but I bought early in the winter, before the advance in price. I also buy bran in car lots.

For several years I have practiced testing my cows with Babcock tester and scales, and by this means have improved the quality of my dairy. Some cows I have tested, showed as high as 6 6% butter fat; but the quantity proved them to be unprofitable boarders, and they were discarded. I am breeding for both quantity and quality, and believe in raising my own cows; have but two out of sixty-five that I did not breed and raise. In feeding my cows, I always consult their individual capacity and ability to convert the most feed to the best use.

Have some of your readers had any experience with silage made from sweet corn? Thinking it may interest them, I will relate what has come under my observation. When I had but one silo, I filled it with Leaming or some of the yellow dent varieties of corn for three years, but after building my second silo, I filled my first with sweet corn, and found that an equal tonnage would feed the same number of cows 33% longer than the yellow varieties, giving each animal what she would eat up clean. I have also found that when changing my cows from sweet to yellow corn silage, they ate more of the latter, but did not give as much milk, nor would they recover in quantity of milk with the same grain ration.

I have practiced this for four years, with the same results. I have always considered it better to feed sweet corn silage the fore part of winter. The tonnage per acre is in favor of the yellow varieties, but I have grown 12 to 15 tons per acre of sweet corn.



For the past eight years I have had at the head of my dairy, registered Jersey bulls, from dams that have produced 14 pounds and over of butter per week, and hoping to further improve my herd, I have recently purchased from P. J. Cogswell, Esq., of Rochester, N. Y. a young bull that I think equal in breeding and individuality to any in the realm of Jerseys. A. L. F.

New York.

Two Wagons at One Price.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn fodder, wood, stones, etc. The man who already has a wagon may have one of these low handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments time. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., Box 130 Quincy, Ill. for their catalogue; which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

FRED TSCHUDY & SON, Monroe, Wis.

Criticism on Plans for a North Dakota Silo.

ED. HOARD'S DAIRYMAN:—I am contemplating building two silos this coming summer, after plans unlike anything I have seen described in your valuable paper; nor do I find in Prof. Woll's book, anything suggestive of the plan I propose. I submit it, therefore, for your criticism, and if faulty in any particular, you will greatly oblige me by pointing them out, as I do not want to make any mistake.

I have a barn 101 x 112 feet, with 16 feet drive through the middle the shortest way, leaving 48 feet on each side. One end is divided into two cow stables, 34 x 48 feet on the outside, with a bay 33 x 32 feet between them; the remaining 16 feet between the bay and the end of the barn is for calves.

The cows stand with their heads to the walls, with a drive way behind them, and feeding alley in front about 6 feet wide. There are stanchions for fifteen head in each of the two rows in each stable, or sixty head in the two stables. Thirty head then will face bay, and thirty head will face the outside walls. The barn has eighteen foot posts, and stands about eighteen inches above the ground; both stables are floored over head, making large storage room for fodder, above.

My thought is to take sixteen feet of the bay next to the calf stable, which will be the middle section of the 48 feet between the drive and the end of the barn, and which will be in the middle and directly in front of the two rows of cows facing the bay. The space, as noted above, will be 16 x 32 feet. My purpose is to make two octagon silos, 16 feet in diameter, with the wood work extending to the top of the barn plates, or 18 feet 6 inches from the foundation, with an excavation four feet, with cobble stone foundation, plastered with cement and a cement floor or bottom.

On top of this foundation bedded in cement, I will lay double sills of 2 x 10, letting the octagon corners of second tier lap by, so as to spike into bottom plank, so these sills cannot spread at corners; then above this, at such a distance as will give me the required strength, I will put another octagon band or girt of two inch stuff, fastening the corners by nailing inch stuff on both sides, and if need be to give it more strength, bend a strap of iron around, letting it extend a foot each way, and spike solid through drilled holes. Then above this second band or hoop, another one at the proper interval, and so on until I get to the top. Then I will board up and down, on inside, with about third class pine flooring, six inches wide; then paper with suitable paper, and board again with heart pine flooring, four or six inches, as may seem best; then paint with coal tar or other paint that will best preserve the wood. It will be seen that the octagon band between the two silos will support the sides to both; the partition studding between the bay and the stables will support two other sides of both silos. It seems to me that this shape will be as good as the round silo, and will have the advantage of being at all times tight; whereas, the stave silo must, of necessity, shrink and swell, necessitating tightening the hoops.

My openings above the second floor will be directly over the feeding alley, next to the bay, and can be dumped down the shutes now provided for hay, and below the floor directly into the feeding alley.

As will be seen, the silos will be sixteen feet from the drive way, where my shredder will stand, so that the carrier will run at an angle of a trifle more than forty-five degrees, and everything under cover.

Sargent Co., N. D. B. P.

The plan proposed is not without merit, but there are two or three points which it seems to us are worthy of reconsideration. In the first place, the machinery and the power for running it cannot be placed in the central driveway. A load of Dakota corn will come pretty near extending from one side to the other, although this is a distance of 16 feet. If a steam engine is used for power, it would necessarily have to be located outside of the barn, and the power communicated to the cutter through the stable. If a tread power is used, it might be set up in the end of one of the stables and the belt run through the partition in the vacant space between the silos and the barn floor.

We would suggest that it would be better to have the openings from silos face the vacant space which opens into the barn floor. The feeding at any given time will all be done from one silo, and it would be quite inconvenient to push a cart into the one feeding alley and bring it out into all the others.

The carriers for elevating the silage can run at a much sharper angle than 45°, It would be practicable, therefore, to enlarge the silos, making them at least 16×20 instead of 16×16.

Thick and Thin Planting for the Silo.

Yield of Nutriment Per Acre.

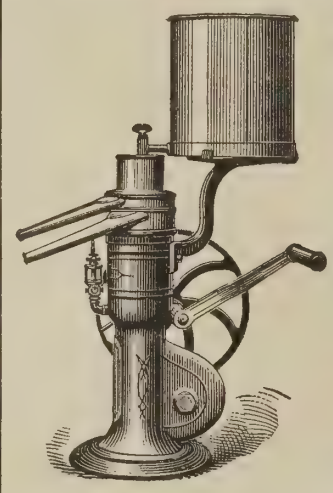
ED. HOARD'S DAIRYMAN:—I have received the following letter:

I have read with much interest, your article in the DAIRYMAN, on the feed value of crops. I infer from what you have written—for you do not say it—that you would plant corn too thick to ear very much, not only for roughage, but for the silo. Or, that if it were eared heavily you would remove the ears before siloing it. Would you do this? In feeding from the silo, we do not, or at least, I have not, discovered any perceptible change in flow of milk, when passing through successive layers of silage rich in ears, and that upon which were few ears.

My conclusion is that if the stalks have attained a fair size, there is little, if any difference. Is this the wrong conclusion?"

Underhill, Wis. W. M. U.

It was not my purpose, in the article referred to, to give any of the figures obtained in our experimental work with the corn



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co 's Color has the highest standing in the markets. . . .

plant, but simply to give the information that an acre of corn planted or sowed so thickly that no ears would form, contained greater feeding value than when planted in hills.

It was merely a figurative illustration, taking the average yield per acre, of ears and fodder in some fifteen different trials in crop experiments at the Minnesota station, and the average composition and digestibility of corn and stover. From this, calculating the feeding value of an acre of hill corn and then comparing it with the feeding value of an acre of fodder corn, using for a basis the yields obtained at this station from corn broadcasted or sowed so thickly in drills that no ears were formed and its composition as found by analysis.

We have made comparisons along this line for three years, planting corn in various ways and at different dates, weighing, analyzing and feeding a given area at intervals of ten days, and the results thus far show that in every case the corn in hills gave the smallest amount of food nutrients per acre, and that late planting produced more protein.

During the past three winters, we have fed to our dairy herd, fodder corn that had formed no ears, and I am satisfied that the final results will show that it is better feed than that having ears. The same is true with silage. That fed this winter contained no ears and we detected no difference as to quantity and quality of milk, though every milking is weighed and tested separately for per cent fat.

I have tables showing the various changes that take place in the corn plant from the time it tassles until it it ripe or is harvested for fodder, but I will only submit one showing the pounds of green fodder, dry matter and protein contained, per acre, under the various methods of seeding.

	Planted.	Harvested.	POUNDS. Green Fodder.	Dry Matter.	Protein.
Hills	May 12	Sept. 11	23,400	5342	392
Single drills	May 14	Sept 11	33,300	7306	387
Double drills	May 14	Sept. 11	33,120	7256	512
Broadcast	May 14	Sept. 11	30,600	7050	502
Double drills	June 19	Sept. 7	42,210	7783	603
Southern corn	June 26	Sept. 7	58,680	1541	647
Sorghum	June 19	Sept 7	61,650	6565	478
Sorghum	June 19	Sept. 20	54,000	9023	434

The rows of corn planted in hills, single and double drills were planted 44 inches apart while the kernels were about two inches apart. The first two years we planted the double and single drills with a Keystone drill and last year the fields of corn intended for fodder corn and ensilage were sowed with a Dowagiac shoe drill, having seventeen shoes five inches apart. The first two were left open and five closed. The next two were left open and then five closed, then two open and one closed which planted the corn about right for ease in cultivating and harvesting with a self-binder corn harvester. By this method three double rows can be planted in going once across the field.

In the latitudes where the dent varieties mature they will give the best results, as cows will eat a larger percentage of the crop. Fodder corn needs from seventy to eighty days from planting to harvesting.

By plowing the field, about the time when it is ordinarily plowed for corn to be planted, in hills' and harrowing it once a week until about the 10th or 15th of June, then planting and harrowing once before and once after it is up, it will not be necessary to cultivate more than once, for at that time of year the soil is so warm that the corn will make such rapid growth that the weeds will be smothered and in the fall the land will be found free from weeds.

When corn is intended for the silo it should be harvested with a corn harvester and the bound bundles drawn to the cutter, as this will save labor in handling it. Cut the twine and remove it before running the corn through the cutter. If it is intended to be fed as cured fodder, put up in large shocks and leave it in the field until it is wanted. It is not safe to stack fodder corn as it contains so much moisture that it will spoil if stacked.

.T L. HAECKER.

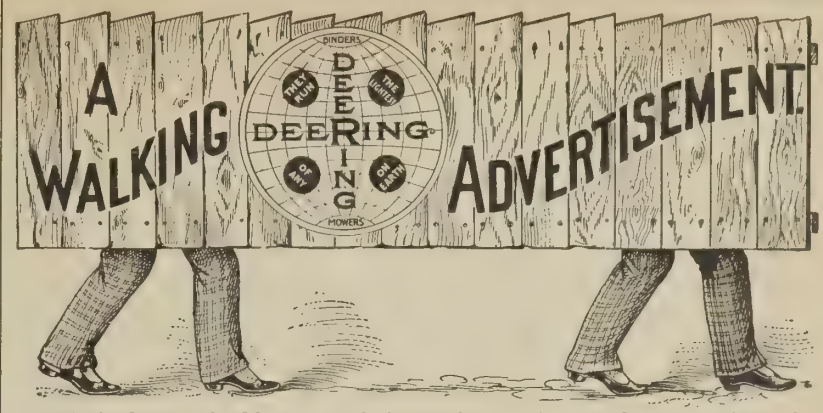
St. Anthony Park, Minn.

PREVENTION OF MILK FEVER.

The following from Dr. Daniel S. White, in *Agricultural Student* prescribes a most excellent method for the prevention of milk fever. If any one has a cow over four years of age, which is a heavy milker, it is well in all such cases to provide against the appearance of this dread disease, for it is invariably the best cows that are taken:

"Allow to pregnant cows plenty of exercise. Cows on pastures which are not too rich are most rarely overtaken by the disease. Heavy grain foods should not be allowed for four weeks before calving, and the bowels kept open with a dose of Glauber salts, which in no case should be given later than ten days before the cow is due to be fresh. The observance of these simple suggestions will positively prevent milk fever's appearance among the cow herd, and as this particular disease is prone to clutch within its embraces the best, most productive and valuable cow of the herd, its prevention means always, from a pecuniary standpoint, a saving to the breeder and dairyman."

"It is hoped that the reader of this short article will not think the less of it because of the simplicity of its suggestions along the line of disease prevention. All that is rational is simple; nothing is more rational than nature, and her most complex phenomena are really marvels of simplicity when we understand them."



A Significant Letter.

ED. HOARD'S DAIRYMAN:—Enclosed find one dollar to renew my subscription for the DAIRYMAN, which I can't afford to be without. The lessons learned in its columns during the past seven years have greatly aided me in increasing the carrying capacity of my farm from 35 to 100 heads of stock, and the average butter production per cow from 200 to 260 pounds.

Let me congratulate you on your issue of March 31st, which I believe was the greatest in the history of the DAIRYMAN, and would make a better text book for farmers than "Stewarts Feeding-Animals". F. W. D.

North Sheldon, Vt.

The above letter shows what it shall profit a man who reads the DAIRYMAN attentively.

Hundreds of thousands of farmers—United States farmers, European farmers, South American farmers, Australian farmers—men who farm for profit—representing the intelligence of the agricultural industry, are walking advertisements for Deering grain and grass harvesting machinery.

Deering machines are profit producers. The harvest season is brief. Very often the weather conditions are such that unless a crop can be saved just "in the nick of time" a goodly percentage of it is spoiled, damaged, lost.

It is just here that Deering machines go in and win the day. Imminent disaster is changed to victory—seeming loss to actual profit.

Deering machines are the *dependable* kind. They stand the test of dire emergency.

That's why the farmers of the world like them, buy them, use them, praise them.

Deering Ideal Binders, Reapers, Mowers, Corn Binders, Hay Rakes and Binder Twine are winners for '99.

DEERING HARVESTER COMPANY, Chicago.

A KIND NEIGHBOR.

The kindest and most neighborly thing one woman can do for another in case of sickness is to tell how she herself was brought out of trouble and distress; and urge her neighbor to seek the same remedy. Hundreds of thousands of mothers have cause to bless just this same kind, neighborly spirit which actuated Mrs. Wm. S. Vollmer, of Concord, Cabarrus Co., North Carolina.

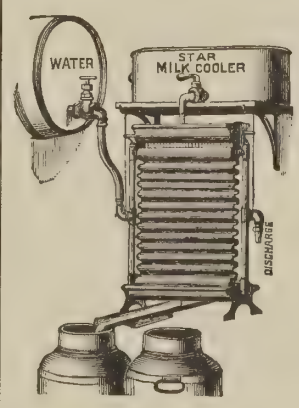
"We moved here to Concord, N. C., over a month ago," she says, in her communication to Dr. R. V. Pierce, of Buffalo, N. Y. "A little girl here was in dreadful health. We told her folks about Dr. Pierce's medicines. I knew what they had done for us. Her parents bought a bottle of his 'Golden Medical Discovery' and of 'Favorite Prescription' and one of 'Pellets.' The patient has improved wonderfully after taking these medicines. I wish everybody knew the great virtue of Dr. Pierce's medicines. I have been using them in my family for three years and always with success.

"I will be pleased to have my letter published. If persons wishing to know more about the great benefits we have received from using Dr. Pierce's medicines will write, enclosing stamp, I will gladly answer."

Every mother of children ought to possess Dr. Pierce's grand book, the People's Common Sense Medical Adviser, a magnificent thousand-page illustrated volume. It teaches mothers how to care for their children and themselves. It is the best doctor to have in the house in case of emergency. Over half a million copies were sold at $1.50 each, but one free copy in paper-covers will be sent on receipt of 21 one-cent stamps to pay the cost of mailing only; or send 31 stamps if you prefer a heavier, handsome cloth-bound copy. Address the publishers, World's Dispensary Medical Association, No. 663 Main Street, Buffalo. N. Y.

ARE YOU PROUD OF IT?

Are you proud of the butter you are making? Has it good grain? Has it the delicious June tint? Is its flavor all right? **Will it stand the Fuller's Earth test for analine dye?** Remember this test can be made in five minutes by any housekeeper, and also remember that if she finds analine dye there, her custom is gone from you forever.



Thatcher's Orange Butter Color

Will give every desired quality to butter that is otherwise all right.

IT PLEASES THE EYE, AS GOOD BUTTER DOES THE TASTE.

It is made from pure vegetable substances, and is healthful. Analine dye is found in many butter colors. It is a deadly poison and is prohibited by law. The Fuller's Earth test will discover it every time. For a Sample bottle of Thatcher's Orange Butter Color, write

With two nails will fasten the cover. Butter makers who care for the appearance of the package use the VICTOR. Strong and smooth. No tacks or sharp corners to injure the hands. **C. E. Smith & Co.**, Westboro, Mass.

The Clover Crop Lost.

How Shall the Farmer Replace It?

The clover crop of southern Wisconsin is a total failure. Every mail brings letters from farmers, asking how to provide pasture for their stock, and to most quickly recover from the severe shock entailed by such loss.

HOW TO GET THE QUICKEST PASTURE.

A field of oats or barley will furnish the quickest pasture it is possible to obtain, barley being a little earlier than oats. Sow oats or barley as for a grain crop, and when the young plants are a few inches high, turn in the stock and treat the field as though it were a pasture. If the cattle do not graze the field evenly, run the mower over the patches where the growth is excessive. By keeping the growth short it will last much longer than if allowed to head out. It is recommended that, as an experiment, clover and timothy seed be sown with a part, at least, of the oats or barley, in the hope of securing a stand for next season. The farmer who can pasture his oat or barley field, and get a crop of clover started at the same time, will be one year ahead. This recommendation must be regarded as an experiment; but it has been successfully tried in a number of cases.

OATS AND PEAS.

Let the farmer also put in a patch of oats and peas. Sow a bushel and a half of peas per acre, covering three or four inches deep on light soil, and one or two inches on heavy soil. After these are planted, sow or drill the oats in the usual manner. Cut the green forage for the cattle, or cure for hay.

MILLET.

For winter hay sow millet or Hungarian grass from the 10th, to the 30th, of June, using from a bushel to a bushel and a half of seed per acre. When the seed heads are coming into blossom, cut and cure for hay. Millet or Hungarian grass will yield from one ton to two and a half tons of good quality hay per acre. Horses should not be given over one feed of millet hay per day.

CORN FODDER.

Any variety of corn will do for green or dry forage, the early kinds being the most suitable for early fall feed. Sweet corn is very satiafactory, because the stalks are soft and palatable. Plant in hills or drills just thick enough to choke the ears down to about half their normal size. Begin feeding as soon as the ears are glazing, and continue with the dry forage throughout the winter. From three to six tons per acre, of winter forage, suitable for all kinds of farm stock, can be secured from a corn crop grown on good land.

Last season the farmers of southern Wisconsin, secured for the first time, in several years, a good "catch" of clover; its loss is little short of calamity. Let no one be discouraged, however, or part with his live stock, but rather let him, by careful foresight, and unusual effort bridge over the short period of difficulty.

W. A. HENRY, Director.

Press Bulletin, Agricultural Experiment Station.

Food Tests of Holstein Friesian Cows.

ED. HOARD'S DAIRYMAN:—Among those of the present official year, not previously given to the public, are the following:

DeKol Manor Beets; age 2 years, 1 month, 15 days; food consumed, pasturage, pea meal 11.83 lbs., ground oats 11.83 lbs., ground barley 11.83 lbs., ground buckwheat 11.83 lbs.; product, milk 307 lbs., butter-fat 9.695 lbs.; representative of Cornell University Station, H. C. McLallen.

Mutual Friend 2nd; age 6 years, 6 months, 26 days; food consumed, ensilage 434 lbs, hay 36 lbs., wheat bran 45 lbs., cotton seed meal 3½ lbs., ground oats 5 lbs., corn meal 15 lbs.; product, milk 427.4 lbs., butter-fat 14 724 lbs.; representative of Cornell University Station, A. R. Ward.

DeKol Lady; age 1 year, 11 months, 2 days; food consumed, pasturage, pea meal 11.83 lbs., ground oats 11.83 lbs., ground barley 11.83 lbs., ground buckwheat 11.83 lbs., product, milk, 312.4 lbs., butter-fat 9.384 lbs.; representative of Cornell University Station, H. C. McLallen.

Aggie Paul, age 2 years, 2 months, 2 days; food consumed, ensilage 203 lbs., hay 7 lbs., wheat bran 28 lbs., oil meal 16 lbs., corn meal 30 lbs., ground oats 14 lbs.; product, milk, 280.3 lbs., butter-fat 11.203 lbs.; representative of Michigan Station, Porter H. Davis.

Clothilde Artis Topsy; age 4 years, 1 month, 10 days; food consumed, pasturage, malt sprouts 21 lbs., gluten meal 7 lbs.; product, milk 412.8 lbs., butter-fat 13.724 lbs.; representative of Cornell University Station, Leroy Anderson.

Paula Dorinda; age 2 years, 10 months; food consumed, ensilage 363 lbs, hay 13 lbs., wheat bran 80 lbs., oil meal 31½ lbs.; product, milk 343.2 lbs., butter-fat 11.101 lbs.; representative of Michigan Station, Porter H. Davis.

S. HOXIE, Supt. Adv'd Reg'y.

Yorkville, N. Y., Mch. 27, 1899.

A Simple Cure for Warty Udders.

I notice that in your last issue a querist signing himself "Drogheda" asks for your advice with regard to the removal of large, rough warts from the teats of one of his cows. The remedy which you prescribe—dressing with lunar caustic—will undoubtedly effect the desired object, but if you will allow me to say so, I think your correspondent will find it an improvement upon the plan which you recommend, if, after smearing his fingers with castor oil, he draws the warted teats gently every day for a few weeks, and then rubs the udder with a little of the oil, so that it will run down along the teats. In this way he will find that the warts can be completely got rid of without any burning of the teats, or any pain to the cow. No one who has not tried it can form an idea of the effect which castor oil has when externally applied on the mammary glands and the teats.—*The Farmers' Gazette, Ireland*

Secretion of Milk.

The following statement concerning milk and its secretion is taken from a very useful little work "Elementary Physiology" by Ainsworth Davis.

It may be said to represent the latest determinations of physiological investigation concerning this very interesting subject.

"The milk glands (the udder) are not merely to be regarded as arrangements by which certain materials are strained out of the blood. The milk tubules are very closely surrounded by a network of capillary blood-vessels and constitute a fitting apparatus so far as the water contained in the milk is concerned. But that a great deal more than simple filtration takes place follows from the fact that casein, milk-sugar and butter fat are not present in the blood, while there are considerable differences between the two liquids as regards the inorganic salts, milk containing for instance far less sodium chloride (common salt) than blood, but much richer as regards potash compounds. In short the protoplasm of the glandular cells, which line the blind ends of the milk tubules breaks down into the simpler chemical substances, casein, milk-sugar, butter fat, etc,, which are therefore produced much the same way as the pepsin of gastric juice, or the ptyalin of saliva. But in this case there is not only a chemical breaking down of protoplasm, but also a *disintegration of the cells*, which so to speak are constantly "moulting". For this reason milk has been termed "dissolved milk gland," using the expression somewhat metaphorically. An interesting proof of this is found in the nature of *colostrum*, the fluid which is secreted by the milk glands just after the birth of the calf, and which differs a good deal from milk in composition. If a drop of this is examined under the microscope, it will be found to contain not only milk globules, but also larger bodies *colostrum corpuscles*, some spherical, some irregular, which are obviously discarded cells.

The constant breaking down, which takes place in a milk gland is counterbalanced by a corresponding process of renewal and reconstruction, the materials of which are supplied by the blood.

During milking the *sphincter* muscle of the teat is relaxed as the result of reflex (or sympathetic) action, so that the milk can flow out of the milk cistern. It has also been commonly assumed that a large amount of milk is actually secreted during milking, as another result of reflex action. The main argument in favor of this view has been that the cavities of the glands are not large enough to contain the amount of milk actually yielded at one time. It must be remembered however that these organs are very elastic and capable of great distension, besides which, careful experiments recently made do not support the usual view.

FACTORS INFLUENCING THE AMOUNT AND QUALITY OF MILK.

In this connection (1) the breed is of very great importance, determining as it does the tendency of the glands to secrete a greater or less total quantity, and to produce milk more or less rich in butter fat. (2) Diet. The essential point is that the food should be rich in albuminoids (protein), the most favorable ration being 1 to 5.4. It is quite a mistake to suppose that an increased percentage of butter fat in the milk results from giving more fat or oil with the food. Careful experiments, made on feeding of cows, show that if anything, the tendency is the other way. From what has already been said on the secretion of milk, it follows that the fat of the food does *not* pass *as such* into the milk, a fact which enables the experiments quoted to be more clearly understood.

A reasonable amount of water taken with the solid food increases the secretion of milk and so does common salt, of which from ½ to ¾ of an ounce may with advantage be given daily to the cow. (3) The state of the *general health* naturally exerts an important influence upon the production of milk for all the organs of the body are more or less interdependent.

It is therefore a matter of *practical* importance to secure the health of cows by feeding them properly, by *ventilation* and *cleanliness*.

Some interesting experiments have been made as to the effect exerted by a proper care of the coat. The amount and quality of milk yielded by a number of cows were carefully determined for two periods of two weeks each, no attention being paid to the coat in the first period, while during the other it was carefully brushed and curry combed every day.

In the latter period the yield of milk was considerably greater, and there was a distinct increase in the percentage of butter fat.

The yield is diminished by exercise, the amount of which should not, therefore, be increased beyond that actually necessary for the health.

(4) The quantity and quality are not constant throughout the period of milk yielding or lactation. The maximum quantity is secreted during several weeks after the birth of the calf, then a gradual diminution takes place.

(5) TIME OF MILKING.

The morning milk is poorer in solids than the evening milk, while that obtained at noon is richer than either. In other words, the longer milk remains in the udder the poorer it is in quality, though at the same time the quantity is greater. Experiment has also shown that three milkings a day are more advantageous than two, the total yield being greater and the percentage of butter fat higher."

CONCERNING OUR ADVERTISERS.

LARGEST WORKSHOP IN AMERICA.

Lasting success does not come in a moment, and true success is never the result of "luck." It takes time and real merit, with plenty of experience and honest effort, to reach the top in anything. The history of the Deering Harvester Co. of Chicago is an example of success on a large scale. With more employes than any other single manufacturing plant of any kind in America, it is now running day and night to fill orders. Since 1891, when Deering machines were put on the market with "bicycle bearings", the growth of the business has been marvelous. The day is not far distant when other manufacturers will be forced to build lighter-draft machines or go out of business.

mous loop lock woven wire fence have put in a number of new machines and otherwise improved their factory, so as to promptly handle their steadily increasing business. These people are among the newer concerns to engage in the woven wire fence business, but this fence was of such good quality as to place them at once upon a firm basis with both the trade and the users of fencing. They make fence of the usual standard heights for various purposes. The method of construction is such that the fence responds readily to both expansion and contraction, and consequently remains tight, avoiding all sagging and looseness. If any of our readers are in need of fencing this spring they will do well to correspond with these people before buying. Ask them for circulars, etc., and kindly say that you saw their ad. in our paper.

THE MOST MODERN MACHINES.

The most modern of all machines in the harvest field is the McCormick. The McCormick anticipates every improvement. The McCormick invariably leads the way. It is the oldest firm in the business, and yet the most up to date in its methods. There is a special satisfaction in owning a McCormick. It makes a man a happy buyer. He knows he has a sure thing when he is in possession of the "Best in the World", whether it be a McCormick Binder, Mower, Corn Harvester, Rake or Fodder Shredder. Everybody knows that the "Best in the World" is the motto of the McCormick Harvesting Machine Company.

CARE OF MILK.

Warm weather is now rapidly approaching and with its coming will also come the usual difficulty in caring for milk. With all that has been said in these columns, touching on this subject, from time to time, our readers should be well informed. As the subject is one of more than ordinary importance, however, we shall again refer to it.

It is not always desirable or convenient for farmers or dairymen to put up a supply of ice with which to cool milk and cream. This is indeed no longer a necessity, as less expensive and equally as effective methods are now within easy reach of all. We refer to the modern milk cooler and aerator. This is a simple, low priced device through and over which the milk is passed, removing all animal odor and any taint that may come from stabling, food, or other cause, and at the same time reducing the temperature to a low point. This retards decomposition, (souring) thus making the milk keep sweet much longer than would otherwise be the case. Many creamerymen and cheese factorymen are now insisting upon aerating in all the milk which they buy. These aerators are made in a variety of sizes, to meet the requirements of large or small herds. A very good aerator and cooler is the "Perfection", made by our advertising patron, L. R. Lewis, of Cortland, N. Y. Write him for circulars, prices, etc.

ED. HOARD'S DAIRYMAN. Ft. Atkinson, Wis., DEAR SIR:—I herewith send you report of the test of Exile's 70th daughter, Exile's Dainty, 107508, 4 years, 8 months old; weighs about 850 pounds; a beautiful cow, carrying a grand udder.

She milked, from Jan. 31 to Feb. 7, seven days, 251 pounds of milk, from which was churned 16 pounds 8 ounces of well washed butter, salted one ounce per pound. This cow milked, in 60 days, from Jan. 1st to March 1st an average of 32 pounds daily. She had no special preparation for the test, and was not unduly forced. I think she is capable of making a higher test.

Rochester, N. Y. P. J. COGSWELL.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

CHRONIC ROUP.

I have a flock of chickens that act as follows: The chicken's eye will water and wink very much, in a few days a bunch will come out between the eye and the bill, or the eye will swell shut. I know it is all caused by the same thing. In the eye will gather a hard substance all around the eye, and will last about a week, when the eye will open again, and you would think that it would be all right. If the lump comes in first above the bill, the eye will be all right, but the hen cannot eat, and is in great pain. After a week or so, I can pick out the lump, it looks like a kernel of corn, well soaked. The hen can eat for some time, and I think they will be well, but it will come on again and again, and the hen is weaker every time; she will get blind and starve to death. G. F. E.

Rogersville, Wis.

ANSWER.

You have unmistakable roup, in a chronic form. If you kept your floors clean and well aired you would not be thus annoyed. Separate all affected ones from the others. The disease is very infectious. Stop corn as food. Chop onions fine, to each pint of chopped onions add two, only, drams of finely pulverized sulphate of iron. This must be so mixed that each spoonful of chopped onion will have just the same amount of iron. Wash all the heads with tar soap and hottish water. Then thoroughly dry and *rewash* with Tilden's Bromo Chloralum, 1 to 8 of cold water. Let two teaspoonfuls trickle down the throat; continue this until well. Most thoroughly disinfect. Burn all old infected nests, all of them; clean, and then keep clean. Roup is always an indication of neglect and of filth in some form.

GARGET.

We have a high grade Holstein cow that dropped her calf about ten days ago, that has a badly caked udder. We had trouble with her last season in the same way, so we commenced milking her two weeks or more before she calved, and have milked three times a day since, but she does not get much better. THE O. C. S. Co.

Parkman, Ohio.

ANSWER.

Nothing you can do will do as much permanent good as full, constant physicking, 1¼ pounds, at least, of salts, and 2 ounces of best ginger. Second dose of 1 pound in 5 days, third dose of 1 pound in 6 days.

Rub udder with strong camphorated spirits six parts, common turpentine two, only, parts; rub hard and long once a day. Much depends upon good massage. Still much more depends upon the physicking.

WARTS.—CLOVER BLOAT.

We have young heifers that have warts almost all over them. What can be done to remove the warts?

What do you advise doing for a cow that is bloated on clover? T. E. E.

Ind.

ANSWER.

Touch each wart with nitric acid, a few at a time; change this acid to butter of antimony every other day. Tie a piece of sponge or cotton batting tightly to the end of a pencil sized stick; rub a little when applying.

Keep her off the clover for a while, then allow a short run, only, until the change takes place, as it will.

SHORT BREATH IN COW.

I have a cow that has trouble breathing. She rattles inside. When full of water, you can hear her breath for ten or fifteen rods. She will jerk herself from tail to head. Worse in damp weather. Milks well and in fair flesh. Been so for six months and is growing worse. H. G.

Albino, Iowa.

ANSWER.

Your cow may have the asthma, or there may be some other of many different ailments. To determine which, requires a personal and close examination by a qualified veterinary surgeon.

BLACKLEG.

The other calf died also, and we think the disease is blackleg. This calf was swollen up, and under the skin it felt like a bunch and being almost black when cut open. We have now taken off the feed of the others except milk, water and hay. We have given them several physics. We have a mixture of equal parts of Epson salts, copperas, and saltpeter. Do you advise this to be given to young cattle, like old, so they can help themselves whenever they want? What medicine do you advise for young calves that seem to run down, cough and finally die? Have you any medicine for pneumonia for cows? What do you think of Fowler's solution for it? Is there any risk in feeding silage as much as they will eat, to young cattle, say, 6 months to one year old? K. & W.

Monticello, Wis.

ANSWER.

You say the other calf died also, I have no knowledge of the other calf, no doubt you have. Looks like anthrax—blackleg. No, I do not advise such a mixture by any means. I do advise an inspection by a veterinary surgeon. No, I have no medicine for tuberculosis. Yes, I think silage is wrong for young cattle.

RETENTION OF PLACENTA.

Two months before calving, my cows were brought two hundred miles by train, apparently all right, till after birth of the calves. Three out of five retained placenta, one for ten days, and one, as we believe, never passed all of it at all. She began to fail soon after calving, and died in three weeks afterwards. Once or twice, after doses of physic, salts, ginger and nux vomica, she discharged offensive matter, and bits of apparently decomposed flesh.

The other two cows responded to the physic, discharged the placenta after a week or ten days, and are doing very well although one seems delicate and gets off her feed every day or so. MRS. B. F.

Valdorta, Ga.

ANSWER.

Shipping pregnant cows, especially so far along, shows poor judgment on the part of the buyer and seller. It is, in all points, wrong.

I can give no advice as to the cows not cleaning, beyond the fact that they did not clean, as you say. All this was, no doubt, the result of the rail road travel, etc. I can't give any further advice than never to ship pregnant cows.

STAGGERS.

A 3-year-old Jersey heifer, in milk since last fall, thriving and healthy, has had a couple attacks of staggers. First time about a month ago, noticed when turning her out to water, her eyes seemed dilated and her legs weak, so that she tottered out of the stable, all right when we brought her in this time after sunning herself for an hour in the yard staggered and almost fell when being put in. J. H. D.

Stonewall, Manitoba.

ANSWER.

Gentle physicking for a while, say 6 ozs. of Epson salts, 1 oz. of ginger, and half a dram nux vomica, give three daily doses, then wait a week, then repeat two doses, then wait a week again, then repeat one dose. If recurrence should take place, give one full dose without the nux vomica. Be careful of the food, not too stimulating.

SWELLING OF TEATS.

Two of my cows were troubled with swelling at the root of the teats. It first commenced with hard lumps, and in the course of time they broke open, and remained open like large pimples, for a long time. Now I have two more that are commencing the same way. W. J. M.

Westby, Wis.

ANSWER.

Neglect, for a long time is bad management. Inject the sore with the compound tincture of myrrh and aloes, daily. Thoroughly physic and repeat. I think, originally, you had cow pox, neglected. Give internally, sixty grains of iodide of potassa each morning, for twenty to thirty days. Keep clean, but don't wash. This will go through your herd if not arrested at once. Use spermaceti and oil of almonds, as an ointment, half and half; use liberally.

THE EFFECT OF A KICK.

A fine Jersey cow, 5 years old, was kicked in the flank on the left side, just forward of the udder, not quite a year ago. After the swelling went down, there was a big "melon" shaped protrusion, which finally settled down to about ten inches in length, and six or eight inches through. It feels to the hand, as if there were small lumps about as large as hen's eggs inside, more noticeable on the under side of this rounded shape. She has a good appetite, is giving her regular amount of milk, and in no way does the swelling seem to hurt her, except that she flinches and tries to kick at one's hand, when it is being felt of. Would the milk from such a cow be considered unfit for human food, by the health authorities of the cities?

Hastings, Ill. S. G.

ANSWER.

There can be little mistake in your case. The kick ruptured the bowel. I know of no permanent treatment likely to do any good. Feeling, as usual, is foolish and annoying to the cow, and can do no possible good. So long as the hernia is not strangulated, she may get along; never allow her to get costive. The milk is good.

NYMPHOMANIA.

What can I do for a three year old heifer that has had one calf and comes in heat once a week, but does not get with calf?

Nebraska. B. T. T.

ANSWER.

Sexual desire must be stopped for several periods by the best antaphrodisiac. There is no other right way.

MILK FEVER.

What caused the death of a valuable Jersey cow I owned? The cow calved at 3 p. m., April 1st; calf came wrong end first; she was only a few minutes having calf; calf died soon after; cow seemed to be in perfect health; cleaned in about 5 hours; she ate and drank all right until 11 o'clock, a. m., April 2nd, but seemed to be weak, soon after laid down unable to get up, did not seem to have any pain, but at 2:30 p. m. was dead.

Hinkley, Ohio. F. W. B.

ANSWER.

Unmistakable milk fever. She ought to have had good daily exercise. All pregnant cows should.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.*

Every bottle sold is warranted to give satisfaction. Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars.

BELLMORE, IND., Jan. 25, 1899.

H. W. KELLOGG, Ripon, Wis.

SIRS:—The medicine I bought of you last winter was fed to two cows and one heifer. The cows have each a bull and heifer calf respectively. Only fed them 3 or 4 doses apiece and caught the first service after feeding the medicine. It has saved us two valuable cows. I can recommend it to persons who have cows in the shape our's were. The heifer was killed after being in calf about three months, and was examined, found with calf. She had been bred several times before.

Yours truly,

W. R. THOMAS.

Dr. Horne's Anti-Abortient

Prevents Abortion and cures Nymphomania—failure to breed; also Emmenagogue Powders for cows failing to come in heat. Both powders are the result of long practical experience and study and may be given in a little moist feed. 5 oz. $1, 11 oz. $2, $3 oz. $4, 50 oz. $8, by mail.

Also Specific for

SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM HORNE, Janesville, Wis.

EVERYWHERE IT IS FIRST THE MAN.

Everywhere that we find an up-to-date paying herd of cows, do we find over them an up to-date farmer. One who does not believe that the less a man reads and thinks on this question the more money he will make.

For instance, here is Mr. John Armstong, of DeSmet, South Dakota. It is only a few years that they have been dairying in that state but if they are successful they come down to the principles, as has to be done everywhere. Mr. Armstrong makes this statement to a Sioux Falls paper:

It may be of interest to your readers to give them a statement of the results of feeding sixteen cows balanced rations for the year 1898.

You know it is well for one to practice what he preaches, and the more I go into the matter of feeding the more I am convinced that the farmers of this state are losing large amounts every year by not feeding the proper proportion of nutriments.

So for the past year I have kept an accurate account of the product of sixteen cows, the cost of feed, and the net income derived therefrom.

My cows are just an average lot, bought as I could find one for sale some three years ago, and the results show what can be done with an average cow with proper care and management.

The yield of milk from the sixteen cows in 1898 was 96,018 pounds, an average of a little over 6,000 pounds each. This milk at the DeSmet creamery was worth $794.76. I base the amount on what I delivered at the creamery and the amount used in four families. Besides rearing the calves on the skim milk, I fed with skim milk and shorts—charged to cows—$215 worth of pork. Now, putting a reasonable value on the calves at the end of the year, $325, gives us a total cash value of $1,334.76. We deduct forty tons of bran and shorts, $240, and say for hay and pasture $94.76, leaving a net balance of $1,000. Profit for each cow, $62.50. The average yield of butter for each cow was 301 pounds and 5 ounces.

The following is the report of Geo. Bickford, a patron of the skimming station, at Livingstone, Wis., for 1898:

Number of cows milked 18, of which 5 were two-year-old heifers, freshening in April; 4 were full blood Jerseys and the balance were grades. Amount of milk delivered at creamery 86,700 lbs., for which he received in cash $678.86. Milk sold to customers by quart $25. Average test 4.5 7-12, making the price per one hundred pounds 78 3-10 cents. Veal calves sold $30. This makes a total $733.86, or an average of $40.77 per cow. This is not counting any skim milk or heifer calves raised.

It should be understood that the two foregoing reports are measured by the result at the creamery, so far as milk and butter is concerned. Both of them show that there is a man at the helm who believes in the cow and in giving her a fair show to do dairy work and bring forth dairy results.

Official Tests Made by Holstein-Friesian Cows.

ED. HOARD'S DAIRYMAN:—These butter tests (made from May 1st, to May 31st, 1898,) are for seven consecutive days, and are supervised by officers of agricultural colleges and state experiment stations, or by persons vouched for by such officers. The amounts of butter fat are determined by the Babcock tests, and the amounts of butter are calculated on the basis of 80% fat to a pound of butter, the rule established at the World's Columbian Exposition.

Rixa Silva's Last 39389; age 2 years, 11 months, 12 days; amount of butter fat, 10.339 pounds; amount of butter, 14.174 pounds.

Lady Longfield 3rd 39945; age 3 years, 3 days; amount of butter fat, 12.894 pounds; amount of butter, 16.114 pounds.

Jessie Fobes 3rd 32286; age 6 years, 1 month; amount of butter fat, 17.11 pounds; amount of butter, 21.39 pounds.

Vevie DeKol 40932; age 1 year, 9 months, 22 days; amount of butter fat, 7.936 pounds; amount of butter, 9 92 pounds.

Johanna Clothide 40384; age 2 years, 6 months, 26 days; amount of butter fat 10 839 pounds; amount of butter, 13.549 pounds.

Johanna Rue 3rd 42167; age 2 years, 29 days; amount of butter fat, 13.477 pounds; amount of butter, 16.846 pounds;

Johanna Aaggie 36477; age 4 years, 5 months, 9 days; amount of butter fat, 18.289 pounds; amount of butter, 22.861 pounds.

Aaggie Paul 40930; age 2 years, 2 months, 2 days; amount of butter fat, 12.574 pounds; amount of butter, 15.728 pounds.

Fannie Douglas 4th 41943; age 1 year, 11 months, 26 days; amount of butter fat, 8.934 pounds; amount of butter, 11.198 pounds.

Ollie Watson 3rd, 41944; age 2 years, 11 days; amount of butter fat, 7.311 pounds; amount of butter, 9.139 pounds.

Francktje 2nd 40125; age 1 year, 9 months, 28 days; amount of butter fat, 8 637 pounds; amount of butter, 10.796 pounds.

Gewina 2nd's Lulu 41945; age 2 years, 17 days; amount of butter fat, 11.959 pounds; amount of butter, 14.949 pounds.

Lottie Lass 19220; age 9 years, 2 months, 3 days; amount of butter fat, 15.75 pounds; amount of butter, 19 69 pounds.

Vrouwkje of Hijlaard 7th 28449; age 7 years, 26 days; amount of butter fat, 14 791 pounds; amount of butter, 18.489 pounds.

Sijtje Twisk Pietertje 38233; age 4 years, 10 months; amount of butter fat, 12.041 pounds; amount of butter, 15.051 pounds.

Hetje 6th's Pietertje 38945; age 3 years, 29 days; amount of butter fat, 11.123 pounds; amount of butter, 13.904 pounds.

Lotty Moselle's Pietertje Mechtchilde 41805; age 2 years, 2 months, 24 days; amount of butter fat, 9.765 pounds; amount of butter, 12.206 pounds.

Hetje 6th's Mechtchilde 41809; age 2 years, 1 month, 7 days; amount of butter fat, 9 001 pounds; amount of butter, 11.251 pounds.

Mechtchilde of Midland 41806; age 2 years, 1 month, 29 days; amount of butter fat, 7.456 pounds; amount of butter, 9.32 pounds.

Midland Gem 41811; age 1 year, 11 months, 19 days; amount of butter fat, 7.916 pounds; amount of butter, 9 895 pounds.

Pietertje Mechtchilde of Midland 41887; age 2 years, 2 months, 1 day; amount of butter fat, 7.732 pounds; amount of butter, 9.665 pounds.

Leda's Princess 2nd's Aaggie Wayne 33591; age 5 years, 10 months, 3 days; amount of butter fat, 16.44 pounds; amount of butter, 20 55 pounds.

La Reina Maud 43380; age 3 years, 7 months, 3 days; amount of butter fat, 13 68 pounds; amount of butter, 17.10 pounds.

Aaggie Paul 40930; age 2 years, 2 months, 2 days; amount of butter fat, 11.303 pounds; amount of butter, 14.129 pounds.

This last test was made to ascertain cost of food per pound of butter. It was supervised as other tests. The cost per pound, as per schedule of prices prepared by the board of officers, was 6.3 cents. S. HOXIE.

Yorkville, New York.

Wetting Feed for Cows.

ED. HOARD'S DAIRYMAN:—In your paper of March 24, '99, No. 6, page 107, last column, near the bottom, you say: Wetting the feed is only an increase of labor. Henry, Feeds and Feeding, page 433, at close of Art. 665 says: This experiment would indicate that slopping is an expensive way to feed cows.

I am cutting my dry alfalfa with a feed cutter into a box, mixing with it equal parts of corn meal and bran, wetting this thoroughly, and giving it to the cows I am milking just before they are milked, and they eat it greedily.

They have, in their yard, plenty of good water at any time, night and day, and twice a day dry alfalfa, as much as they will eat. They have pasture in the forenoon.

Not long since, my cutter broke down and I was compelled to stop this feed and give them dry corn meal and bran. Now my cows may not know what is best for them, but they immediately let me know that it was an "expensive way" for me to omit their wet cut feed, as they dropped off from one to two, each in the amount of milk they gave at a milking.

The cutting and wetting of this feed is quite an increase of labor and cost of keeping cows, and if I can omit it without loss of milk I should be glad to do so.

Dona Ana Co., N. M. A. M. H.

It is frequently the case that changing feeds will cause a slight change in the amount and quality of the milk given. After a sudden change, it may be a week or more before the animal returns to her normal flow of milk. Consequently it is hardly safe to judge of a method of feeding from a few days' experience.

The quotations from HOARD'S DAIRYMAN and *Feeds and Feeding* relate exclusively to grain feeds. We have frequently advocated the moistening of corn stover and other coarse fodder and letting it lie long enough to heat and soften.

Transfers of Guernsey Cattle from March 15 to 31, 1899.

Ruptured 20 Years

WONDERFUL CURE OF A WELL KNOWN CITIZEN OF WISCONSIN.

R. M. Wilsie's Good Fortune in Overcoming His Affliction.

It is a piece of good fortune to relate the fact that there is a cure for rupture. Some people contend that only a surgeon with a knife and a needle can bind the broken place together, but

MR. R. M. WILSIE, Brandon, Wis.

the experience of R. M. Wilsie, of Brandon, Wis., completely upsets this theory.

There is a doctor in Adams, N. Y., who has discovered a marvelous system of treatment that not only retains any kind of a rupture, but also causes the muscles to grow together. Mr. Wilsie heard of it and gave it a test. The results were astonishing.

Although 61 years of age and badly ruptured for more than twenty years, Mr. Wilsie began to mend at once and was perfectly cured in a remarkably short time. Today he is hale and hearty, a fine looking gentleman and completely restored from the slightest trace of rupture. He naturally recommends the system highly. His cure excited considerable interest among his neighbors, many of whom were also ruptured and who have since been cured.

The system of cure is the discovery of Dr. W. S. Rice, one of the best known rupture specialists in the country. He has recently issued an illustrated book on the subject of rupture and sends it free to every one; his object being to disabuse the public mind that rupture cannot be cured. The beauty of his system is the absence of all pain; absolute immunity from danger; no operation of any kind; and not the loss of a minute's time from work. This is a subject well worth inquiring into. Thousands of people have friends who are ruptured and they will do them a lifelong service to tell them of this new and marvelous home cure. Send for the book. It is free to all. It fully explains the system of cure and is immensely valuable to all who are ruptured. Write at once to Dr. W. S. Rice, 353 L. Main St., Adams, N. Y.

ROBERTS' ANTI-ABORTION SERUM

Hypodermatically administered, is a **POSITIVE CURE** for abortion in cows. SWORN testimonials furnished on application. **Dr. D. ROBERTS,** Veterinary Surgeon, Address, **Waukesha, Wis.**

KANSAS CITY, MO., March 15, 1899.

MORRISON MFG. CO., GENTLEMEN:—With regard to your Heel Plate, we would say, it is increasing the sales on your plows very materially. It is easy to appreciate that it is a decided improvement in walking plows. It is the greatest advance made in walking plows for ten years, and that is saying a great deal. Yours truly. BUFORD & GEORGE MFG. CO.

It makes Share last longer, cures winging over, holds the Share sharp twice as long.

A postal will bring a beautiful catalogue.

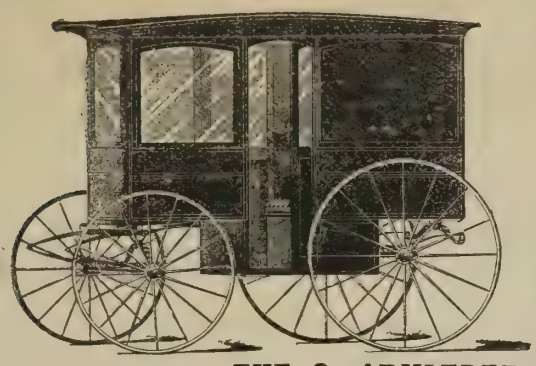
For grinding crushed ear corn, shelled corn, oats, any kind of grain mixed or separate for stock feed; table corn meal, buckwheat, rye and graham flour for family use.

THE BEST MILL FOR ALL FARM USES.

The most durable. Largest capacity. Less power. Finest grinding. No expense. Easiest handled and kept in order. Make no mistake, get a **Buhr Mill,** it will pay best. *Our new book on Mills of over 85 sizes and styles now ready.* Send for it.

NORDYKE & MARMON CO., Flour Mill Builders, 25 Day St, Indianapolis, Ind.

THIS PERFECTION MILK COOLER AND AERATOR



is a simple device for cooling and aerating milk. It quickly and effectually takes out all animal heat, and with it all **animal odors,** odors arising from **stables, feed, etc.** This method of treatment makes the milk keep sweet much longer. It is better for making **butter, cheese,** etc., and will stand shipment much better.

Cost But Little and Last Indefinitely.

They are made in sizes from 1 to 200 cows and will quickly pay for themselves in the increased reputation they give your product. They come very nearly taking the place of ice in warm weather. Send for illustrated catalogue and prices of **Farm and Dairy Supplies.**

L. R. Lewis Mfr., Box 10, Cortland, N. Y.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

THE ONLY LOW-DOWN

Short Turn
Straight Bottom
Short Coupled
Light Draft Wagon
on the Market.

20 INCHES from ground to bottom of body. Will turn as short as any cut under reach wagon. Strong construction, nicely finished. Send for Catalogue, prices and terms. Wagons for carrying bottled milk a specialty.

SHIPMAN, BRADT & CO.,
Sole . . . Manufacturers,

We ship our goods anywhere for examination

and guarantee and warrant everything. Send for our large Illustrated Catalogue—FREE.

Elkhart Carriage and Harness Mfg. Co. W. B. PRATT, Secretary. **Elkhart, Indiana.**

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY.
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premum.

or

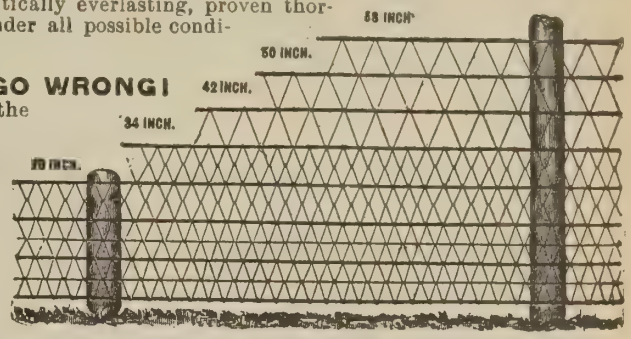
Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.



IF YOUR PASTURES AND FIELDS ARE INCLOSED WITH THE

ELLWOOD ALL STEEL WOVEN WIRE FENCE

you have secured absolute efficiency at least expense, in a practical fence that will positively turn cattle, horses, hogs and pigs. A fence that is strong, practically everlasting, proven thoroughly efficient under all possible conditions.

YOU CAN'T GO WRONG! in selecting the **ELLWOOD WOVEN FENCE.**

Sold by our agents in every town. If you can't get it in your town, write us direct, and we will see that you are supplied.

ELLWOOD FIELD FENCE (Standard Style)

AMERICAN STEEL & WIRE CO. General Offices: **CHICAGO, ILL.**

WHERE GOES YOUR MONEY WHEN YOU BUY FENCE?

Lots of it goes into the dealer's pocket. Why not save that amount? How? Buy your fencing from us.

We sell the **ADVANCE FENCE** direct to the farmer at wholesale. The dealer can't buy it any cheaper than you can. It is equal in quality to the highest priced fences on the market. Completely interwoven—no loose ends to unravel. Circulars and discounts free.

ADVANCE FENCE CO., 4004 Old St., Peoria, Ill.

Just closed. If every reader had **had a Binder** and now had the complete volume with index bound, its value would be increased greatly.

Get a Binder

now for the present volume and preserve the copies in handy form for reference and reading.

BINDER BY MAIL POSTPAID, 75 CENTS

MORE MILK FROM THE COWS.

When the pasture goes in the Fall, the milk goes, the butter goes, the flavor goes until all are shortest when price is highest.

Wilbur's Stock Food

is the same to the cow as sarsaparilla and good diet are to the human. It tones and invigorates the cow, sustains the flow of milk and the color and flavor of the butter.

If your feed dealer, harness maker, druggist or grocer does not keep it, send 50 cts. for a package containing 40 feeds and sample of White Rock Hoof Packing. Our booklet, "Pasture in Packages," tells how you can give your animal the benefit of pasture and at the same time keep him working or in the stable, tells how you can keep up the cow's flow of milk, fatten the steers or hogs and save grain in feeding any animal.

WILBUR STOCK FOOD CO.
179 2d St. MILWAUKEE, WIS.

GLUTEN FEED.

CHAPIN & CO., Milwaukee, Buffalo, Boston, St. Louis. Manufacturers' Agents for **GLUTEN FEED.** This is the best and cheapest milk-producing feed for the money. Contains 26% digestible protein. It keeps sound and sweet. Sold in car lots. Inquire of your grain dealer. Price based on its milk-producing value. For Wisconsin orders address **CHAPIN & CO., Milwaukee.**

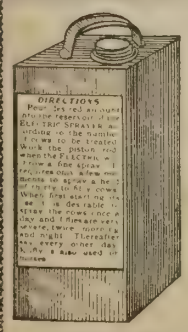
"PURIFINE" A BOON TO THE GREAT DAIRY INTERESTS.

A POWERFUL **Disinfectant** That is ODORLESS, NON-POISONOUS. Used in Creameries, Cheese Factories, Dairies and Stables.

IT DOES NOT Create an Odor to Destroy One.



SAN FRANCISCO, SEPT. 22nd, 1896.
I have used "Purifine" in cleansing milk cans and bottles and find it will remove the bad odor left by old sour milk more effectually than anything I ever tried.
E. A. GREEN, Sec'y,
Millbrae Dairy Company, Mission & 9th.

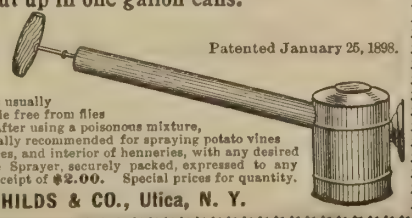
Applied with large quantity of water, which makes it cheap and convenient of use. It is invaluable to the cleanly dairyman or factory operator. Once try, you'll never be without.

SEND $1.00 FOR SAMPLE GALLON by Freight.

This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY AT ONCE.

FITCH CHEMICAL COMPANY, Bay City, Michigan.

KILFLY.



More Milk, More Money, More Comfort for Cows and Milkmen.

A Liquid Mixture of Untold Value.
Applied with Childs' Electric Sprayer.

Protects cows from the torture of flies, thereby increasing the amount of milk. Absolutely harmless to man or beast.
Put up in one gallon cans.

Once Tried, Always Used.

ELECTRIC SPRAYER Patented January 25, 1898.

Convenient and Practical in Every Particular.

Throws a very fine spray of any of the liquids and mixtures usually used for destroying insects, bugs, etc., and for keeping cattle free from flies during the summer weather. Can be thoroughly cleaned after using a poisonous mixture, which is conveniently done by removing the cover. Especially recommended for spraying potato vines with Paris green, also all kinds of plants, bushes, vines, trees, and interior of henneries, with any desired formula. Sample Lot—One gallon can KILFLY and one Sprayer, securely packed, expressed to any address (except in State of Maine) charges prepaid, upon receipt of $2.00. Special prices for quantity.

Salt Surety

Is a good thing to have and costs little to get. It costs fifteen cents extra on every ton of butter to have a salt you can absolutely rely on. That is the first cost of using

DIAMOND CRYSTAL SALT

but, the fifteen cents comes back in fifteen different ways before you are through with it. It comes back in a saving of time, in added flavor to the butter, and weight. More—but why enumerate when the book, "The Salt that's all Salt," tells the story complete. It is yours for the asking.

DIAMOND CRYSTAL SALT CO., St. Clair, Michigan.

IN THE FACTORY.

The U. S. Takes the Cake.

POYNETTE, WIS., Jan. 20th, 1899.

Have been running U. S. Separators since 1892, and can cheerfully say that the new No. 1 Improved U. S. Separator takes the cake. When the skim milk is tested it shows only a trace of fat. I won the sweepstakes and three other first prizes, amounting in value altogether to $115.00, at the 1898 Wisconsin State Dairymen's Association, and all because my No. 1 U. S. Separator makes such smooth, perfect cream.

R. M. BUSSARD, Prop. Bussard's Creamery.

AND IN THE DAIRY.

Very Durable, Very Easy to Operate, Never Out of Order.

TIFFIN, OHIO, Nov. 28th, 1898.

Have used the No. 5 Improved U. S. Separator nearly three years and do not think it is worn a particle. It runs as smooth as the day we first started it. **It is the best separator in the world,** it is so easily run and so easy to clean, and it is always in order to do the best of work. We wonder how we ever got along without one. We think very much of the enclosed gearing. You have the best machine I know of in running and mechanical construction.

We are the only firm that builds factories complete, put them in operation and guarantee results.

THE

Willard Knapp Cow Tie

Still the Dairyman's Ideal.

Mr. DAVID ROBERTS, Breeder of Jersey Cattle, Moorstown, N. J., Writes Us:

"I have given your ties a fair trial and am very favorably impressed. If the cows could talk, I believe they would shout for joy and say delightful. I write to know your best price on twenty more."

All orders reaching us through the HOARD'S DAIRYMAN until May 1st will be DISCOUNTED 10 PER CENT to introduce our Ties in a new field.

SEND FOR FREE CIRCULAR.

Subscriptions in United States and Canada $1.00 per year; 6 months 50 cents; 3 months 25 cents.

FOREIGN SUBSCRIPTIONS may be sent through Sampson Low, Marston & Co., St Dunstan's House, Fetter Lane, London, Eng., or their agents, including the leading news dealers and book sellers in nearly all foreign countries.

All countries in the Postal Union $2.04 a year; not in the Postal Union $2.56.

Correspondents must not expect us to acknowledge the receipt of letters containing remittances for subscriptions. The receipt of the DAIRYMAN is sufficient notification that the money has been received. The label on the paper will show date to which subscription is paid. In case of renewals if date on label is not changed within two weeks after remittance is sent, inform us at once.

Remit by draft on Chicago or New York, or Post Office or Express Order; never by personal check.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

To show up this dust question in stables, some experiments were made at the Illinois station with sterile plates exposed for half a minute in various places. The following collections resulted: Dust from fodder 263; dust from corn meal 5; dust from brushed cows 869; under unwashed udder 2,023; under washed udder 90.

WHICH IS THE BETTER COW?

We have this week pictures of two Guernsey cows, both imported in 1895, by Hon. Levi P. Morton, of New York, and so far as we know still owned by him. The cuts came to us without any accompanying letter of description or explanation, and except as we may judge from the pictures we do not know whether they are good cows, or simply ordinary cows, or poor cows, or which is the better, if there is any choice. Perhaps it is better this way, and better also that we should omit discussion, and invite correspondence and criticism from our readers.

Being imported animals there is very little that can be learned concerning their ancestry, and they, therefore, stand before us simply on their individual merits, as exemplified in their respective forms. The question is: Which of these is the better cow, and why?

We would like a hundred answers to this inquiry—not that we can publish them all, but we could select a few that would be representative and interesting.

It will be excellent discipline for any dairyman, and especially for the young men, to make a close analytical study of these pictures and write out his conclusions, and the reasons therefor. There is more or less both of similarity and dissimilarity between them,—certainly enough to make a choice not altogether easy.

We suggest that not too much importance be given to the matter of position, as it is not possible to make every cow take the most acceptable "pose" before a camera.

AS TO PARTNERSHIPS.

It occasions no little surprise that the patrons of creameries and cheese factories are not more jealous of their individual rights. They constitute, in fact, a partnership; and in all partnerships it is the duty of each partner to do whatever he can to further the interest of the partnership, and to refrain from doing whatever will militate against those interests. There are partnerships in all kinds of business—mercantile, manufacturing, and in practicing law and medicine. What would be thought of a mercantile partnership if one of the partners who, either from carelessness or by design, should so conduct himself as to cut down the profits from 10 to 25%? or the manufacturing concern wherein one of the partners would tolerate such laxity in manufacturing, that the greater proportion of all of the goods made, would have to be sold at a discount of 10 or 20%?

In what essential respect would conduct, such as this, differ from the management of too many creameries and cheese factories where the parties, responsible for the conduct of the business, allow one or more of the patrons to deliver milk in such a condition, that it contaminates the whole product, and makes it impossible to sell it for the best price?

We are not at all disposed to overlook the short comings of the butter maker or cheese maker, or relieve him from the responsibilities incident to his position. He ought to have a judgment sufficient to make a first-class product, when furnished with first-class material. In addition to this, he ought to have ability to determine whether the material furnished him is first-class, second-class, third-class, or worse, and then he ought to have the nerve to reject all the material offered, that will not make a first-class product. But it is worse than useless for such a man to attempt to do himself justice, or the creamery or the cheese factory justice, unless he is supported by a preponderance of sentiment, which demands that he shall exercise this ability and discretion.

If there are slovenly or careless patrons (partners in the business, remember,)who cannot or will not take such care of their cows, the milk and the milk utensils, that they can furnish sound milk, and that which is free from taint, of course they will be offended, and unless they will reform their methods, the sooner they withdraw from the partnership, the better will it be for the business. The sooner they quit delivering milk the better it will be for the other partners, and, we may add, the better it will be for themselves. Discipline is as essential among the patrons of a creamery or cheese factory, as it is in an army. It is not a pleasant task to discipline a soldier, put him on extra duty, or otherwise subject him to punishment, but the good of the whole must not give way to the perverseness of the individual.

It is a well known fact, that at all the dairy conventions held last winter in the central, western and northwestern states, the exhibits of butter scored exceptionally low, and there is no other way to account for it, except on the theory that some of the milk received, was not up to standard; that, in practically all the creameries, one or more of the patrons had persistently and habitually delivered milk that contaminated the whole mass, and made it impossible for the butter maker to turn out a first-class product. Makers that in previous seasons had butter that would score 95 or better, fell down this year to 90 points and below. Is it reasonable to conclude that they have lost their cunning, that they cannot make as good butter this year as they did last year, and the year before? If it had only been now and then a maker that fell below the standard, we might attribute it to carelessness on his part, but when the product of practically all the creameries in the land scores so low, the conclusion is irresistible that there was, somewhere, some general cause for it. The defect was not noticable in texture, color, salting or packing, but everywhere in flavor, and flavor is the one thing more than all others over which the maker has least control. It is the one thing for which the patrons themselves are most responsible.

ROSE OF THE QUARTIERS, A. G. C. C. 8654.

This is not an indictment of the patrons as a whole, or of any considerable proportion of them, in the matter of the milk they individually delivered. One can of off flavored milk is sufficient to impregnate a vat full.

VILLET'S GEM, A. G. C. C. 8664.

With these facts staring them in the face the wonder is that 19 patrons will suffer the twentieth to deliver this contaminating milk. They ought to rise in indignation and insist that they should not be made to suffer in this way. Every creamery and cheese factory in the land ought to call a meeting of its patrons without delay, and by a vote, not only authorize the buttermaker to reject all imperfect milk, but demand that he do this, and give him to understand that his tenure of office depends upon doing this. And when the maker does it, they ought to stand by him like a rock, utterly unmoved by sympathy or any other consideration.

The cheese making season, in Wisconsin, is opening. There are factories in this state habitually receiving from ½ to 1 cent per lb. above the current market price. The cheese that is turned out is always extra, there is no loss on it, it commands a ready sale, it stimulates further purchases. On the other hand, there are factories, too many of them, which habitually receive from ½ to 1 cent(or more) less than current market price.

Why is this? If the maker is at fault, discharge him at once and get some one who can do better; but before doing this be sure that he is at fault, and not some one or more of the patrons.

Every factory in the state, and for that matter, in the United States, should be furnished with the Wisconsin Curd Test. This simple and inexpensive apparatus will enable the patrons, or a committee of the patrons, to determine whether the maker is as fault, or the patrons, or whether the fault lies with only one or two or three patrons. More than that, it will enable the patron whose milk is found to be defective to locate the trouble in his own herd or on his own premises.

There is no question but that the habitual use of the Wisconsin Curd Test in any factory will add very materially to the income to that factory, and if it could be used in all the factories in the state, it would result in enhancing the value of Wisconsin's cheese product by hundreds of thousands of dollars, annually.

We are particularly anxious that every cheese maker who reads HOARD'S DAIRYMAN should be eminently successful. We know he will find the Wisconsin Curd Test of great assistance in attaining this success. It will as infallibly detect milk that is not fit for cheese making as the scales will detect short weights, or the Babcock test detect skim milk, and it will furnish the evidence to support its conclusions. If not already familiar with it, drop a postal card to the Wisconsin Experiment Station, Madison, Wisconsin, requesting a copy of the bulletin which explains it.

We have written on this subject many times before and may recur to it many times in the future, but were specially moved at this time by the receipt of a very brief communication from one of the patrons of a creamery in Minnesota, which reads as follows: "Several of the patrons of the creamery to which I deliver milk have been keeping their milk in the cow stables and horse barns this winter, and it has cut our price down very materially. Talking don't do any good. Will you please give the farmers a broad hint on this subject?"

The Wisconsin Curd Test is especially designed for cheese makers, but the butter maker can often use it to locate the patron whose milk is cutting down the quality of his butter and convince him, and all other patrons as well, if necessary, what the trouble is and where it comes from.

C. W. SWITZER, of Sleepy Eye, Minn., makes the following report of his last year's work in dairying. He states that off of 40 acres of land, he realized $1,080. He milked 16 cows and for this milk he received $680; the increase from the cows was 14 calves, woth $140; he raised and fattened for market $120 worth of pork, and has on hand $120 worth more of pork; he also got his own butter off the land, which his creamery tickets show was worth $20. As a further advantage he turned back upon the land fertilizer from his barns that made the fields better than they were when he commenced operations. Of course, there was some work necessary to care for these cows, but as an offset to this work, he also got forage for seven head of work horses off this land, and he estimates this forage worth at least a dollar a day for seven horses.

When two currents of blood unite to form a third of still greater power, we say they have "nicked" well.

It has been noticed that grade Ayrshire cows bred to a registered Jersey or Guernsey bull seem to produce a superior class of cows. Several of the finest business herds in this country are of that foundation. We cannot account for this except that the Ayrshire "nicks" well with the other strains. But, as we said before, so far as we have observed the same result is not so surely seen when the cross breeding is between Holstein and Jersey or Guernsey. The prepotency of the Holstein is very pronounced and does not readily yield, even in a grade, to a harmonious compromise with other blood.

Others may have had different experience and observation, and we shall be pleased to have them give their experience in the DAIRYMAN.

EFFECTS OF BORIC ACID.

Dr. J. Jameson Evans says that the increasing use of boric acid for medicinal and preservative purposes is sufficient reason for a further record of some effects which have been produced by the drug, when given internally. Quoting a case where it had been given, he says:

An erythematous rash spread over the man's face and head, his salivary glands became enlarged, and eventually the hair on the face and head fell out, so that in a fortnight he was perfectly bald. I have administered boric acid in many cases, and when it has been given for some time, have noticed a rash, followed by a fine scaly exfoliation. I can only conclude that this was due to the action of boric acid on the skin.—*Popular Science.*

If boric acid is absolutely without action, except on bacteria, it is strange that it should be given as a drug. The above would indicate that it has a very decided action on the human body, as well as on bacteria.

A POINT ON STABLE VENTILATION.

HOARD'S DAIRYMAN considers that the cows and all cow owners who want to preserve their cattle to health and profit, owe a debt of gratitude to Prof. King, of the Wisconsin Agricultural College, for the efforts he has made to instruct cattle owners as to the best methods of ventilating stables.

The great danger to the dairymen in these severe northern climates is the fact that in order to secure a flow of milk in winter, they must (1) preserve a certain degree of heat.

(2) There is no way of economically warming a stable except by animal heat of the cows.

(3) To preserve this heat, the stable must be made tight, and consequently the air soon becomes foul and poisonous.

How to build a stable that shall at once be warm and well ventilated was shown by Prof. King, in his admirable lecture before the last meeting of the Wisconsin Dairymen's Association at Green Bay. We heard a score or more of dairy farmers declare that that lecture was worth a journey across the state to hear, and yet there were but few of the thousands in Wisconsin who need such information, there to hear it.

We have often wondered, when stepping into some close, foul stable, if the owner really knew and realized what he was doing. In the old days stables were well ventilated, but they were cold, and but little milk was expected. The following illustration will show the fearful weakening effect upon cattle of breathing foul air.

In Appleton's Encylopedia, 1875, page 125, Dr. Parks, in his article on "Practical Hygiene", gives an instance from the cattle plague in Europe, in 1866:

In cattle sheds containing twenty or thirty cows—which the owners kept closed to such an extent that all chinks in the doors and windows were stuffed with straw and matting, under an ignorant belief that thus the plague could be kept out—very frequently the entire stock died in two or three days after the first appearance of disease; while in other cases, where the animals were housed in a well-cleaned and tidily-kept shed, with a plentiful supply of fresh air, not only did some of them escape the disease altogether, but the deaths were reduced one-third of the number of beasts attacked."

THEY NEED A BETTER DAIRY EDUCATION.

Not long since we received a statement from an intelligent farmer and dairyman, concerning the poor success of a creamery in his neighborhood.

The report he made set us to thinking over the hundreds of similar instances we had known. "The difficulty," he said, "is, that our farmers do not understand this dairy business well enough to make a creamery succeed. And what makes it worse is that no one can get them to see that they need information. They all think that they know enough to handle cows. So they do in their way, but there is no money in their way.

I tried to get them to see that fully a quarter to a third of the returns was in the skim milk, if they handled it right. But a majority of them voted to sell the whole milk for the year at 70 cents a hundred. That forced myself and three more of the heaviest patrons out, for we could not afford to throw away 15 to 20 cents a hundred on our whole year's production, just because the majority of our neighbors did not know the value of skim milk and would not learn. I called a meeting of the patrons, and took with me several copies of the DAIRYMAN and read to them reports of men who told what they were making out of their skim milk with calves and pigs. Then I said to them, 'Why don't you read and post yourselves on this dairy question as long as you are going into it as a business?' I can't afford to trot along with you and lose money just because you are willing to, and are not willing to learn better. There is too much at stake for any of us to be ignorant of our business, and the skim milk is a part of the business.'

Well, the meeting broke up in a row, and our creamery is plunging along and will probably bust up soon, for lots of the patrons say they can't afford to milk cows at present prices of butter.

It makes me mad to see such stupidity. They say they can't afford to milk cows at present prices, but they *can* afford, every mother's son of them, to keep a lot of cows that no man can afford to milk, that has any sense of what he is doing. And then, they *can* afford to throw away the value of their skim milk, and they can afford to be wasteful and unthrifty in lots of other ways, but they can't afford to learn to do better. Can you tell me what can be done with such a community?"

The only advice we can give is to keep up courage. Be patient, but keep everlastingly at them in one way and another. They are like everybody else. When they see their way they will follow it. But it is no wonder that they have not the best cow sense, skim milk judgment and all other kinds of good dairy judgment. Indeed, it would be a wonder if they did have all this.

Men who have never devoted any time to the study of a subject, can not know how long or how wide it is, nor can they know clearly where it touches them. If these men had been readers of what other men were doing, things would look different to them.

Any intelligent man can do wonders in the way of helping up his neighbors, and in getting them to adopt more profitable methods, if he will only keep his temper, use a little good tact and lots of faith.

Get them to read on these subjects all you can, for they can not travel and see for themselves how other men use the better method and obtain the reward of the better knowledge.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By PROF. H. L. RUSSELL.]

Second Series, XIII.

GLOSSARY.

Enzootic—Said of an animal disease, when it occurs continuously in any section of the country.
Haemoglobin—The red pigment in the red blood corpuscles that gives the color to the blood.

TEXAS FEVER.

One of the diseases of cattle that is of more than usual interest in this country is that of Texas fever. On account of its wide spread distribution, and the very peculiar way in which it is disseminated, it is one of the most important animal maladies that we can consider. Again, our interest in it is awakened because it marks one of the triumphal victories that our National Department of Agriculture has scored in its work for the stock interests of the country.

While the disease is commonly called Texas fever, it must not be thought that the Lone Star state enjoys the distinction of being the only region where the disease is thoroughly "at home." Many different names have been given it, the more important of which are southern cattle plague, acclimation fever, or red water disease. The disease is enzootic throughout a number of the southern states and territories, and it is now pretty generally believed that the disease occurs in other continents, although the peculiar nature of the malady renders it difficult to determine these points except by comparative studies.

PECULIARITIES OF THE DISEASE.

This disease has been a puzzle for many years. While its communicable nature was self-evident, it acted so differently from the majority of infectious diseases, that the rules that have proven of such value in the study of these failed to solve the question of the cause and manner of distribution of the infective agent for many years. The disease does not show itself so severely on southern cattle as it does upon those with which these cattle come in contact. When the southern cattle are shipped or driven north to utilize the wide ranges of the west, a pathway of disease is frequently noted. For many years before the true nature of the disease was established, it was maintained that these southern cattle in some way spread poison and disease among northern herds. Generally this transference of the disease does not occur directly, but pastures and pens occupied by southern cattle are in some way affected so that when fresh cattle are put in them, they acquire the disease. Frequently, the spread of the disease is limited in a very peculiar way. Cattle in one field will acquire the infection, while in a contiguous pasture they will remain free. To such an extent is this true, that close observers even asserted that a barbed wire fence seemed to stop the progress of the disease, although it was also noted that the wash of an infected field onto another piece of land was often sufficient to contaminate it.

The disease frequently breaks out when northern cattle are imported into the south, they seem so be so much more susceptible than the native southern cattle. The name, acclimation fever, comes from this characteristic,as it was thought that northern cattle acquired the disease, before they became inured to southern conditions.

With most infective diseases of a febrile type, the period of incubation is generally short, but in Texas fever a period of about a month elapses before the disease breaks out. It is evident that this disease presents peculiarities that differentiate it from most other contagious maladies.

For many years, it baffled the skill of all investigators to determine the cause and manner of its spread. A study of the animal in a diseased condition, and also post mortem examinations showed that the disease was not caused by bacteria. It had been determined by these examinations, that one of the most salient characteristics of the disease was the destruction of the red blood corpuscles in the blood. Another symptom was the appearance of a bloody urine, a condition produced by the excretion of the blood pigment (haemoglobin) through the kidneys. This peculiarity gave the name red water to the malady.

Finally, the clue to the disease was obtained in the affection of the blood corpuscles. Some years ago, it was discovered that malaria was caused by a micro-parasite of animal origin that had the power of attacking the blood corpuscles and destroying them. This analogical condition led to a most careful examination of the blood of animals with Texas fever, to find evidences of a similar parasite. Dr. Theobald Smith was finally able to demonstrate that such a parasite existed. He proved conclusively that such an organism grew and multiplied in the blood corpuscles, and that their bodies were destroyed by the parasite. The causal relation between the disease and this form which belongs to the animal world, rather than to the bacteria, was thus placed beyond dispute, for by introducing the blood of an affected animal, containing the organism, into a healthy cow, the affection could be artificially produced. Unfortunately, it is impossible to grow these animal parasites on culture media, as we do bacteria; therefore the study of them is rendered much more difficult.

MANNER OF INFECTION.

How this organism finds its way into the susceptible animal was still an unsolved problem. The idea had gained ground as a result

of the experience of cattle owners, that the disease was propagated by cattle ticks, but no satisfactory proof for this had ever been adduced. As a result of the investigations of the United States Department of Agriculturel, it was shown that the cattle tick did serve as a vehicle for the transmission of the disease. When southern cattle are shipped north in summer, they are infested with cattle ticks. As these mature, they drop off the animal, lay their eggs, which also contain the micro-parasite. In the course of three or four weeks the young ticks appear, and attach themselves to the cattle. The bites from these infect the animal, and the disease then appears. This accounts for the prolonged period of incubation, that is to be noted in skin disease.

The working out of this relationship, between the organism of Texas fever and the manner in which it is introduced into the susceptible animal, shows how important it is to carry on thorough investigations by competent investigators.

The many peculiarities of the disease are now readily explained on the basis of this relationship. The apparently nonsensical statement, that a barbed wire fence could stop the disease, appears rational when one understands that these cattle ticks cannot migrate far, and that the longer grass under the fences would prove so serious an obstacle, that they could not readily go from one field to another.

No sort of an efficient treatment, or even prevention could be instituted so long as the cause, and its manner of distribution remained unknown. When these points were thoroughly established, the basis for a rational treatment of the question was made.

If the cattle tick could be killed, then it would be possible to prevent the spreading of the disease. A study of the life history of the tick, showed that during the winter months no danger need be apprehended in the shipment of cattle from southern to northern states. The result of these studies were to institute a quarantine power, and a quarantine boundary across which cattle could not be transported during the closed season. This quarantine service has been of great importance in limiting the distribution of the disease.

After the relation of the cattle tick to the disease had been established, rational attempts could be made toward prevention. This was done by experimenting on methods of disinfection, that would destoy the ticks on the cattle without affecting, seriously, the animals themselves. After a large number of unsuccessful attempts to find a "dip" that was satisfactory, success has finally been attained in the use of paraffine oil. This destroys the ticks without seriously irritating the skin of the animal. To insure complete destruction, it is necessary to dip twice, with an interval of a few days, but this can readily be done, and it is confidently expected that the inauguration of this method will result in the saving of millions of dollars to the stock owners of the south.

FEEDING ANALYSES.

We republish herewith a revised table of feeding analyses, compiled from what we believe to be the most authentic and reliable sources—largely from Prof. Henry's book on Feeds and Feeding, a work we most unhesitatingly commend to the attention of every man who wishes to become a progressive farmer.

The figures given are the averages of a great number of chemical analyses and digestion experiments, and will thus be somewhat too low for feeds of extra good quality, and too high for those of poor quality or in poor condition.

We have, in deference to the practice of the experiment stations, changed the first column from organic to dry matter—the only difference being, that the latter includes the mineral matter or ash of the feeds, a portion of which is utilized by the animal.

The amounts given are the quantities of the different ingredients found in 100 pounds of the feed named. Thus in 100 pounds of mixed pasture grasses there are, as an average, 20 pounds of dry matter, and in this dry matter there are 2.5 pounds of digestible protein, 10.2 pounds digestible carbohydrates, and 0.5 of a pound of digestible ether extract, or fat.

TABLE SHOWING THE AVERAGE AMOUNT OF DRY MATTER AND DIGESTIBLE NUTRIENTS IN ONE HUNDRED POUNDS OF THE SEVERAL MORE COMMON AMERICAN FEEDING STUFFS.

	Dry Matter.	Digestible Nutrients.		
		Protein.	Carbohydrates	Ether Extract.
GREEN FODDERS.	Lbs.	Lbs.	Lbs.	Lbs.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained, by some, that the fat in the milk comes, largely, from the crude fat in the food, but ithas been demonstrated that it is not absolutely necessary, for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein	Carbohydrates.	Ether extract.
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

OATS, PEAS AND BARLEY—BEAN PICKINGS.

Will you please tell me through the columns of your paper, in what proportion to mix peas, oats and barley for growing, where the grain is fed to horses and milch cows?

Can you give me the relative value of bean pickings ground into meal? That is, the amount of protein, etc. H. C. W.

Ellisburg, N. Y.

We have some doubt whether oats, peas and barley could be successfully grown together, because of the differing periods of ripening. One trouble in raising oats and peas is that if sown at the same time the oats get too ripe before the peas are ready to harvest. To overcome this we sow the peas from a week to ten days before the oats. Barley ripens earlier than oats and this circumstance would augment the inconvenience.

We suggest sowing oats and peas at the rate of 1½ bushels of each to the acre and omitting the barley.

We have no figures on the feeding value of bean pickings, and because of the varying quality of these pickings, we question whether any reliable figures could be had. What we do know is that beans are rich in protein and a very concentrated feed. They should, therefore, be fed somewhat sparingly and never without mixing with some lighter feed, like bran or oats, with careful observation of results from day to day and being governed thereby.

AN IOWA RATION.

Please give me a balanced ration of the following: Wheat bran $10 per ton, corn, shelled, 26 cents, oats 23 cents, barley 30 cents, oil meal $1.40 per cwt. Plenty of good clover hay, and cows run in corn stalks in good weather. W. H. L.

Cooper, Iowa.

We very much doubt whether milch cows derive any benefit from roaming in a stalk field even "in good weather." There is a limit to the cow's capacity for eating, and when she fills, or partially fills, her stomach with old, weather beaten, juiceless corn stalks, it detracts, pro rata, from her ability to take other and better feed. It is almost as impossible for the cow to make milk out of this kind of fodder, as it would be for her owner to make a silk purse out of a sow's ear, and as profitless, too. Such fodder will sustain life, but it bears about the same relation to well cured corn stover that the stone and copper implements of the races which preceded us in this land bear to the highly tempered and polished steel implements we are permitted to have.

The long and the short of the story is, that it is not good feed,—not so good for cows as was the miscalled "canned roast beef" for our army boys in Cuba and Porto Rico.

Moreover, there was great waste in letting these stalks stand out in the field. Less than one-half of the feeding value of the corn crop is gathered when only the ears are saved. The great enemy of the farmer, and especially of the dairy farmer, is waste. Every large legitimate fortune in the land was started and maintained by saving those things which others throw away. Allowing a valuable food product to become deteriorated is only one of the ways in which waste occurs. There is great waste in keeping two cows to do the work that one ought to do; great waste in feeding an excess of carbohydrates and too little protein; great waste in not providing comfortable quarters for milch cows; great waste in unkindness.

This inquiry, with some half dozen others, was received at a time when we could not possibly keep up with the demands upon our time and space, and was buried under a mass of accumulated correspondence, or it would have been answered some weeks ago. We regret this very much. Possibly our friend may have found in the numberless answers to other inquiries some formula fairly well suited to his conditions. We are almost certain he could have done this, if he had read with half the care that the importance of the question merits.

If we had given a formula early in March, it would have been about as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. clover hay	16.94	1.36	7.16	.34
4 lbs. bran	3.52	.50	1.54	.12
4 lbs. corn chop	3.56	.32	2.67	.17
1 lb. oil meal	.91	.29	.33	07
1 Totals	24.93	2.47	11.70	.70

If there had been some good corn stover (well cured corn stalks) available, 7 pounds of such fodder might have been substituted for 5 pounds of the clover hay.

ROUP.

My chickens eyes will water and wink very much. In a few days a bunch will come out between the eye and the bill, or the eye will swell shut. I know it is all caused by the same thing. There will gather a hard substance all around the eye, and it will last about a week when the eye will open again, and you would think that it would be all right, but the hen cannot eat and is in great pain. After a week or so I can pick out the lump; it looks like a kernel of corn well soaked. G. F. E.

This flock of fowl is affected with roup, a contagious disease among poultry. It is caused by damp quarters or being kept in open quarters in damp and cold weather. First, I would suggest removing the causes, clean out the coop well and keep it dry, scatter a generous quantity of lime throughout, whitewash the walls and nests and paint kerosene oil on the roosts. Remove the sick fowl from the flock. Having done this, the disease will disappear. In a well advanced case, it is best to kill the fowl, but upon the first appearance of the disease it can be easily cured. Clean out the nostrils and inject kerosene (a small sewing machine oil can is good for this). Feed soft feed with a stimulent, such as red pepper. D. E. ROBERTS.

Fort Atkinson.

LINING A SILO.—TARRED PAPER.

I expect to build a silo this summer. Will build of double boards put on perpendicular, inside course planed, but not matched. Will it be better to put a double lining of tarred paper between the lining at an extra cost of $2.00, or will one lining be sufficient?

Baxter, Pa. C. H. T.

Two thicknesses would be better than one, first, because there is apt to be some defect in the paper, which the second thickness would be likely to overcome, and second, the double lining would be more durable, thus postponing the necessity for repairs.

A GEORGIA RATION.

Give me a balanced ration of the following feeds, only ones available here: Cotton seed meal $20 per ton, bran $18 per ton, corn meal $21 per ton, cotton seed hulls, $7 per ton. You will certainly confer a great favor upon me if you can give me a balanced ration of this, that will be a healthy

feed for my cows. They are new to the section, having recently come here, are fed and milked at 3 a. m., watered and turned into five acre grass lot at 7 a. m., where they have one acre of good shade. At 3 p. m. they are fed and milked again and remain in the barn until next morning. The DAIRYMAN is my only help in trouble.

Valdosta, Ga. MRS. B. F.

First of all, see to it without delay that something in addition to cotton seed hulls be provided for roughage as soon as possible. Sow some cow peas at once, and when they are fairly well grown, cut and feed green. Cut and cure for hay what are left, and be sure to have enough to last until other forage is available. Hulls do very well in moderate amounts, but they are very dear fodder at $7 per ton.

We advise for present use a mixture of cotton seed meal, corn meal and bran, in equal parts by weight, and feeding from 6 to 9 pounds daily, mixed with an equal amount in bulk, of hulls. The amount to feed to each cow must be governed by her ability to respond. In addition to the above let the cows have what they can gather from the pasture and all the hulls they care to eat.

FOAMING CREAM—ABNORMAL FERMENTS.

1. What causes cream in the churn to foam and swell, so that it will all stick to the walls of the churn?

2. Why does the milk from cows short of lactation, sour quicker than if they have been milked for a length of time?

3. Why is it that sometimes cream will thicken before it sours, and other times it will get very sour, and yet not thicken?

Wooler, Ont. J. C. A.

1. Thin cream churned at a low temperature will frequently foam and swell so that it will nearly fill the churn. Thin cream churned below 55° will frequently foam and give trouble. A thicker cream is the remedy.

2. If the milk is clean and kept in a cool place, it will not sour any sooner than milk from fresh cows.

3. It depends on the kind of ferment you have in the cream. Some forms of bacteria will thicken cream without any acid being formed. You may also have a ferment that will make the cream so viscous that it will not churn under any conditions. In both cases there is an abnormal ferment in the cream, which should be removed by thorough cleaning and scalding of the milk utensils and the introduction of the proper lactic acid ferment in the form of a starter.

PRESERVATIVES FOR MILK.

What will keep milk sweet, and how much to the gallon? E. C. F.

New Castle, Pa.

Do not use any preservatives in milk. You are only preparing trouble for yourself in the future. See that your utensils are kept clean and scalded with boiling water; keep your milk in a clean, cool place and you will have no need for antiseptics of any kind.

COLORADO RATION.

Would like formula for ration from bran at $15, corn chop (fine) at $15.50, cotton seed meal at $22 and good silage and alfalfa hay. Is there any benefit in cutting the hay for the cows, if we feed the grain with the silage? C. C. P.

Denver.

Alfalfa hay at $7 per ton furnishes protein to better advantage than cotton seed meal at $22, or bran at $15, and we therefore suggest as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
25 lbs. silage	6.60	.33	3.50	.18
12 lbs. alfalfa hay	10.99	1.32	4.75	.14
8 lbs. corn chop	7.12	.63	5.34	.34
Totals	24.71	2.28	13.59	66

For cows in full flow of milk and capable of responding to more generous feeding, the grain may be moderately increased, and possibly it would be wise to give variety by using bran for this purpose.

There will be less waste, if the greater part of the hay is chaffed and mixed with the silage, or otherwise moistened and allowed to soften somewhat. Alfalfa, if not cut when quite green, is very apt to have more or less large stems, containing a surplus of woody fiber.

MILK DEALER'S ACCOUNTS.

T. M. D. states that his business, as a milk dealer, has outgrown his present method of booking. He asks how the large dealers succeed in keeping the accounts of their numerous customers. Who of the DAIRYMAN readers can help him?

PRESERVING COMPOSITE SAMPLES.

Can samples of milk be kept for the Babcock test, for two weeks, by chemicals, so that the fats will be unimpaired? In other words, can cheese factories that test their samples by the Babcock test, twice a month, get as fair tests as those that test once a week? SUBSCRIBER.

Easton, Pa.

Bichromate of potash is the substance usually used for preserving composite samples of milk.

Use 8 grains for every pint of milk to be preserved. This can be measured best by taking a .22-inch pistol cartridge shell, cut to ½ inch long. This, when loosely filled with powdered bichromate of potash, will hold enough to preserve ½ pint. The composite sample should have a light straw color, if the proper amount of preservative is present.

If too much is used, the solution of the casein in the acid is rendered difficult—so much so as to interfere with the proper performance of the test.

If the proper care is used in taking the test from the composite sample, accurate results can be obtained when testing but once a month. In general, the oftener the test is made, the better.

DIVIDING OVERRUN.—SILO FOR FIFTY COWS.

How much is the overrun on 100 pounds of butter fat? Should the patrons be paid for butter fat or for total butter? Is it right that the patrons should have the overrun when the patrons pay all the expenses? How big a silo is required for fifty cows?

Grantsburg, Wis. P. J. P.

The average overrun is about 15% but it may vary from 12% to 20% according to conditions.

The patrons should be paid according to the amount of butter made. After all expenses of manufacture have been deducted, the net amount should be divided according to the per cent of fat furnished by each patron.

Fifty cows will require about 180 tons of silage. A round silo to hold the above amount will be 19 feet in diameter by 30 feet deep.

LICE ON ANIMALS.

I have lice on some of my cattle, what can I do to get rid of them? X. Y. Z.

Staten Island, N. Y.

The remedy which has given the most satisfactory result is kerosene emulsion, made as follows: Kerosene, two gallons; common or whale oil soap, one-quarter pound; water, one gallon. Heat the solution of soap and add it boiling hot to the kerosene; then churn the mixture for ten minutes. Dilute the emulsion with twenty gallons of water and apply with a spray pump. If no spray pump is at hand, drive the animals, if many are to be treated, into a narrow chute and apply the emulsion with a common watering can, being careful to treat all parts of the body.

THE CLOVER IS KILLED.

All over Wisconsin, Northern Illinois and in much of Michigan, Iowa and Minnesota, there is a great complaint about the clover being winter killed. In Southern Wisconsin we have yet to hear of a single piece, new or old seeding, that will pay for leaving. In many instances alfalfa is also killed.

Now, this is just the time to make arrangements to grow oats and peas for hay, to take the place of the clover.

Be sure to fit the ground well, making a nice seed bed, and use plenty of seed, not less than two bushels to the acre.

It is of the *utmost importance* that the peas be *planted deep*. The best and surest method is to sow them broadcast and plow under four to five inches deep, roll the ground, and a week later, harrow well and sow on the oats.

Oat and pea hay is the best substitute we know of for clover hay. Read what Prof. Henry says on page 220 and what J. R. H. says on page 217, both in last week's issue. There is no time to be lost in this matter.

THE MAN—THE COW—THE RESULT.

Twelve years ago C. H. Phelps, a Marshaltown, Iowa, school teacher, landed at Belmont, Northwestern Nebraska, with a team of horses, one cow, fifteen dollars cash, and a large family, and himself in poor health. He determined to become a first-class dairy farmer although there was no sort of encouragement in the wild surroundings about him, for that sort of farming. He had sufficient education to appreciate the value to any man of good knowledge, of the aid that good reading in his line would give him. This is a big thing in favor of any man whether he lives in Nebraska or Massachusetts. He has gone on doing the right thing according to the best intelligence he could get.

Twelve years have rolled away and how is it now? He owns a large farm, and lives in a large and comfortably furnished house. He has a large barn with a well arranged underground stable, a splendid silo, which he believes is one of the sheet anchors in dairying even though he lives where "cheap food" is the cry. He has a herd of nearly forty Holstein cows, a good hand separator, and is an all around up-to-date dairyman. All this has been done, starting clear down at the bottom round of the ladder, in twelve years.

We know of young men who started with the gift of a farm, a herd of cows and a cash balance in the bank, one might say at the top of the ladder, who are today sitting on the bottom round. The *Up to Date Farmer*, from which we take the above facts, well says: "Few attempts have been made to develop the dairy industry there (northwestern Nebraska), but it will only require a few men like the enterprising and ambitious Phelps to bring it to the front."

Here again do we see the everlasting truth of the statement so constantly made by HOARD'S DAIRYMAN, that it is not the state, location or community, which governs success or failure with cows, but rather the qualities of the man himself. It is not a matter of luck, or special providence, but of special manhood. "What man has done man can do." If Mr. Phelps can make such a success, in a region that is not a dairy section, what ought not other men to do with every aid and assistance about them?

Of Interest to Cheesemakers.

Mr. T. B. Millar was for several years one of the most successful of the traveling cheese instructors in Ontario and is now manager of the Thames Dairy Company. His past experience and his present employment are sufficient guaranty that what he has to say about cheesemaking is worthy the attentive consideration of every cheesemaker, no matter how long he has worked at the business.

We especially want to emphasize what he says below in regard to rejecting all milk that will not make good cheese. Of course, there is a right way and a decidedly wrong way for doing this. It can be done in such a way as to win the respect and esteem and gratitude of the patron, or it can be done so as to be extremely irritating and offensive. Choose the right way. If a certain patron's milk is suspicious call his attention to it in a quiet, personal and strictly confidential and not too positive manner. Tell him that you are having trouble and that you fear it comes from something in his milk. Ask him if he has any reason to suppose that there is anything wrong with any of his cows or his help, or his surroundings, and suggest that it would be a good plan to test the milk with the Wisconsin Curd Test, and explain how it works. Tell him that such a test will surely decide whether you are right or wrong. Nine times out of ten the patron will say go ahead, but if he demurs, simply say that you are sorry not to have his co-operation, take the sample and ask him to look at the results the next day.

Do not say anything about the matter to other patrons or outsiders. In other words, do as you would like to be done by if the situations were reversed and you were the patron and he the cheesemaker.

Meantime read what Mr. Millar has to say about cheesemaking in general. We copy from the *Farmers' Advocate:*

For cheesemaking, only milk that is clean, sweet and free from bad flavors should be used. To the cheesemaker I would say inspect closely all milk delivered at your factory, and reject anything that will not make good cheese. Having carefully selected the milk, heat gradually to 80° or 86°, stirring frequently and gently to keep the cream from rising and the milk from scalding on the sides of the vat. After the heat is up to the desired temperature, make a rennet test immediately to ascertain the degree of ripeness If the milk is working slowly, a small quantity of nice flavored starter would be an advantage. Set the milk so that it will dip in

"The Mill Cannot Grind with Water That's Past."

This is what a fagged out, tearful little woman said in telling her cares and weaknesses. Her friend encouraged by telling of a relative who had just such troubles and was cured by Hood's Sarsaparilla.

The little woman now has tears of joy, for she took Hood's, which put her blood in prime order, and she lives on the strength of the present instead of worrying about that of the past.

Neuralgia—"I had dreadful neuralgia, miserable for months. Neighbors told me to use Hood's Sarsaparilla; it cured me perfectly." MRS. FRED TURNER, Barre, Vt.

Erysipelas—"My little girl is now fat and healthy on account of Hood's Sarsaparilla curing her of erysipelas and eczema." MRS. H. O. WHEATLEY, Port Chester, N. Y.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Does the Milk Taste Cowy?

: : : : If it does it injures it for either sale milk or for Creamery or Cheese factory purposes. Get a Champion Milk Cooler-Aerator and it will remove that trouble. It aerates and cools your milk instantly, saves time and labor, and makes you money. Our free book "Milk" for the asking.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

from 2¾ to 3 hours with from ⅛ to ¼ inch acid. Use enough rennet to cause perfect coagulation in from 30 to 35 minutes (I am now speaking of summer cheese), allowing the curd to become fairly firm and to break clean over the finger before cutting.

Commence cutting with the horizontal knife, cutting slowly, then follow at once with a perpendicular knife, but with this knife, to make a good job, it is necessary to draw it quickly through the curd, and thus secure a clean cut, instead of driving the curd before the knife. Generally speaking, cutting three times is quite sufficient, but if the knives are coarse, or if agitators are to be used, I would recommend giving an extra cut. Stir gently for 10 or 15 minutes, and see that the curd is free from the side of the pan before turning on any steam. Then heat slowly for the first 15 or 20 minutes, taking from 35 to 45 minutes to raise the temperature to 98°. After turning off the steam, stir continually for 15 or 20 minutes, and occasionally after until the curd is ready for dipping. In most cases it is advisable to run off part of the whey soon after the heating is completed, and see that the curd is well cooked before sufficient acid for dipping has been developed.

Dip the curd with from ⅛ to ¼ in. acid, and by the hot-iron test, and have the curd in such condition that it will not require much stirring in the sink. Have the curd from 4 to 6 inches in the sink, and leave until matted sufficiently to turn without breaking, then cut in strips about 6 inches wide and turn often enough to keep the whey from gathering in pools on the curd. When turning the second time, it may be doubled, always turning the cold ends or sides in and thus secure uniform maturing.

Mill the curd when it becomes flaky and will show from 1¼ to 1½ inches acid by the hot-iron test. I would not be guided altogether by the amount of acid, but by the acid and the condition of the curd. I would use a mill that would leave the curd of a uniform size and not too large. After milling, air well by stirring, and if the curd were maturing slowly, I would pile deep and stir out frequently. Air and mature well before salting; salt according to the amount of moisture in the curd, and the length of time you expect to hold the cheese in the curing room, for the curing room must also be taken into consideration. Usually from 2½ to 2¾ pounds of salt to 1,000 pounds of milk is about right quantity. As soon as the salt is dissolved, put to press and see that the temperature is not over 85° or under 78°. Apply the pressure slowly at first, and leave the cheese in the hoops for 45 minutes before bandaging. Pull up the bandage neatly and trim off the shoulders that are almost sure to be on them. Put back to press, turn in the hoops in the morning, and see that they are finished in first-class shape before being taken to the curing-room.

THE UTAH DAIRYMEN.

The Utah Dairymen's Association recently closed its Annual Meeting, and a wide-awake and profitable session it was. Somehow we always read the proceedings of these newer associations with great interest. There is a freshness of spirit and a conquering faith in them that takes us back a quarter of a century, when the associations that are now old stayers were then in the forceful believing age. President Hanson in his annual address emphasized a truth that cannot be dinned into the ears of all of us any too much That was, the value of strong laws against adulteration and counterfeiting of dairy products. Where a state has such laws and there is a strong public sentiment behind them for their enforcement, the cow and her product then holds the market. On this point he said:

'Six years ago there were at the outside eight creameries or factories in the state and the amount of milk handled by the majority of these was quite limited. The greatest difficulty we had to contend with at that time was the marketing of our produce. Carload after carload of oleomargarine and filled cheese were shipped into our markets, all of it sold to the consumer as the pure article.

The result was practically to shut the Utah dairymen out of the consuming centers of the state. At the present time there are six times the number of factories there were in 1894, and I believe ten times the product is manufactured in them. Yet, though prices are lower, as they are lower all over the United States, we sell this very largely increased production just as easily, if not more so, than we did the smaller amount. The factories of the state distributed nearly a half million dollars the past year to the farmers supplying them with milk. When we consider that this income is almost a direct gain without any decrease, rather an increase in other farm products, the advantages of this dairy development become still more prominent."

When it is considered how hard it is to get the dairy farmers of the country to see the necessity of a strong fight all the time to prevent being driven out the markets by fraud; how hard it is to induce more than a few to contribute even a trifle to defend their own livelihood, and still more, how many can be found throwing cold water on every effort of manly defense. The words of President Hanson show that it is worth while to stand up like men in defense of the cow and her honest product.

Cream Testing Station.

An Important Step Taken by the Maine Dairymen's Association.

ED. HOARD'S DAIRYMAN:—The lately organized Maine Dairymen's Association has just taken an important step in the interest of the dairy industry in the state and sets an example for other dairy states, which might be followed, perhaps, with profit to farmers.

This is in establishing a state testing station, where the several individual samples from creameries, representing the cream of the different patrons, can be tested by an expert.

A meeting was held early in April, plans were formulated and action taken to carry out the work outlined. This was to properly fit and equip with necessary appliances a room, and put in charge a competent and reliable man, with such assistants as he may need, to do the testing, keep the records, and be responsible for the details in the management of the station, under the direction of the executive Board of the Dairymen's Association.

Of course, it is expected that many, if not all, of the creameries of the state will eventually come into the plan and have the testing which forms the basis of the distribution of each patron's proportion of money for cream furnished the factory, done at the testing station. A large part of the creamery managers have already expressed a desire to do so.

The managers of the creameries will, at the end of each month or period, send their composite samples by express or otherwise, to the testing station and in due time receive back their empty bottles and certified results of tests.

The business as previously carried on in Maine, and generally so in other dairy districts of the country, has carried with it an element of uncertainty, not to say of distrust, among the patrons of the creameries.

From the very first use of the method of apportioning the proceeds of the creamery by the Babcock test, the whole matter of sampling, testing, reading, recording and reporting the quality of the patron's cream, has been left entirely in the hands of the men who bought it of them.

This one sided way of doing business has long been recognized and deplored by prominent dairy workers. The feasibility of adopting something like the present plan was first presented at the State Dairy Conference at Portland, last winter, by Prof. G. M. Gowell, Professor of Agriculture, at the University of Maine, Orono, when he urged that a testing station be established to stand between the cream producers and the creamery managers.

While there has ever been questioning and more or less dissatisfaction with the test, as it has been conducted, the real purpose of the station is to place the whole matter above any chance for suspicion.

The Association was fortunate in securing the hearty co-operation of Mr. E. L. Bradford, manager of the Turner Center Dairying Association, and who had already fitted up a testing room in their large new creamery building at Auburn, who readily assented to rent this room for the purposes of the testing station, and have all the testing of this creamery—sufficient in itself to employ the testing station half the time—done by the station.

This, so far as I know, is the first testing station ever established in this country in the interest of the creameries and their patrons.

Maine. L. F. ABBOTT.

Partly Skimmed Milk for Cheese Making.

ED. HOARD'S DAIRYMAN:—At our annual cheese factory meeting the question arose: Shall we skim the cans? The cream raised by gravitation from milk held over night at home in the late fall as the weather grows cooler. The argument in favor of skimming was that the milk was richer in butter fat in the fall, and it was impossible to work it all into the cheese. Consequently, the whey vat received the excess of fat that might be skimmed off at home and converted into a saleable article. The inference was that the cheese was just as good, and the butter from the night skims was clear gain. The difference noted on the increase of butter on the whey vat proved it.

Those opposed to skimming said: The difference in the selling price of the cheese more than overbalanced the gain derived from the night skims, and the whey vat was no indication of the loss claimed, but the increase in the amount of whey butter in the fall was due to the change of weather; that those little devils that make things sour were not quite so active as the cool weather approached, hence, the wrong impression that there is an avoidable waste.

FRED LITTELL. N. Y.

If the only argument in favor of part skimming is the old one, that fat may be, or is wasted by running away with the whey, it is an exceedingly poor excuse.

A good cheese maker will lose but little fat in working up either rich or poor milk. The whey should not contain over .35% fat even from 5% milk, and if a cheese maker loses more than that, it is time for the patrons to ask, why?

To allow the patrons to part skim at home, is to introduce a very disturbing element into cheese factory practice, especially if the milk is pooled without testing. If skimming is to be done at all, it should be performed at the factory, so that there will be some uniformity as to the quality of cheese made.

We do not think it advisable to skim at all, but think that the factory should be so equipped as to make either butter or full cream cheese, according as to which product will bring the best returns.

AT a meeting recently held by the executive committee of the Kansas State Dairy Association, it was decided to hold the next meeting with the usual program and exhibition of butter and cheese, at Manhattan, Kansas, November 22nd, 23rd, and 24th, 1899.

At the same time the Association will have the honor of dedicating the new agricultural building, for which the late legislature appropriated $25,000, and which will, practically, all be used for various purposes connected with the dairy industry.

In Pain?

In the Back?
Then probably the kidneys.
In the Chest?
Then probably the lungs.
In the Joints?
Then probably rheumatism.

No matter where it is, nor what kind; you need have it no longer. It may be an hour, a day, or a year old; it must yield to

Dr. Ayer's Cherry Pectoral Plaster

Immediately after applying it you feel its soothing, warming, strengthening power.

It quiets congestion; draws out inflammation.

It is a new plaster.

A new combination of new remedies. Made after new methods. Entirely unlike any other plaster.

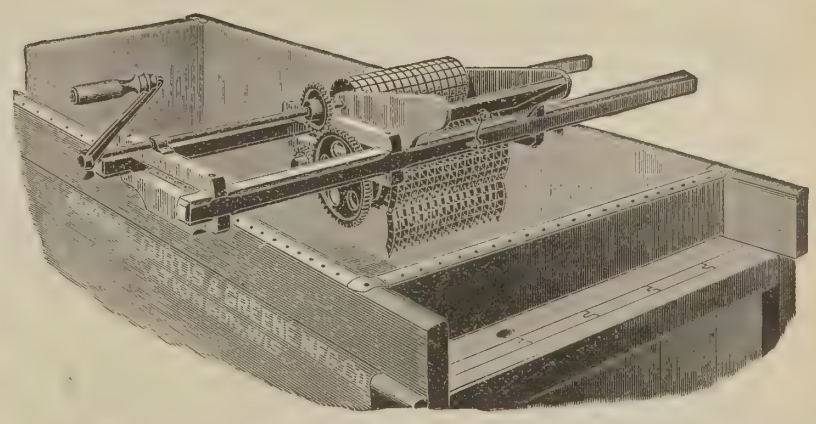
The Triumph of Modern Medical Science.

The Perfected Product of years of Patient Toil.

Placed over the chest it is a powerful aid to Ayer's Cherry Pectoral in the treatment of all throat and lung affections.

Placed over the stomach, it stops nausea and vomiting; over the bowels, it controls cramps and colic.

Placed over the small of the back, it removes all congestion from the kidneys and greatly strengthens weakness.



For sale by all Druggists.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00.**

Calf Scours and Tuberculosis.

PAPER NO IV.

ED. HOARD'S DAIRYMAN:—Tnere are evidently many people in the world who do not appreciate the value of undertaking the causation of disease, and in using such knowledge in treatment. The aggregate loss to dairymen from diarrhœa (scours) in calves must be immense, yet very few seem to be aware that preventive treatment is all important.

Here and there a writer in the DAIRYMAN is impressed with the effect of improper feeding, as a cause, but I have not noticed that anyone seems to have had a very thorough grasp of the subject—a grasp relatively as great as any ordinary physician has in his knowledge of diarrhœal maladies in the human infant.

Of course, much is yet to be learned in both cases—especially in connection with the relation of bacteria to such diseases. The very first thing a doctor of medicine does, in treating a case of diarrhœa is to find out the cause and to remove it. Alleviation and counteractive treatment follows.

The farmer, so far as possible, should understand the hygienic conditions impossible to health. Scours in calves may be due to general constitutional weakness resulting from defective hereditary tendency, or to an environment of foul, depressing air, or it may be due to the action of some specific disease germ; but both these causes are infrequent. In the great majority of cases, it is due, as it is in the human infant, to defective feeding, and much to over feeding.

Especially is this so in regard to too much feed being given at one time. The stomach of the calf is small and its function at first, weak. If too much feed is introduced at one time, the stomach is overdistended, which further weakens its digestive functions, and before the food can all be digested and absorbed, bacterial fermentative changes occur, producing irritating and paralyzing products, and then bring on the catarrhal action known as scours.

In a lesser degree the quality of the feed given induces this malady. In a certain few cases, too large a proportion of fat in the milk may be the cause, but in a much larger proportion a deficient quantity is the trouble. Skim milk is not a healthful food for calves. The fat is needed to supply easily produced energy in the animal and to prevent the cheesy coagula in the stomach becoming too dense and tough, and too large in size, and difficult to digest.

It may be all right to avoid over fattening in a calf intended for dairy purposes, but it was very poor economy to start out such an animal in its career with a weakened or drained alimentary system, especially when butter fat sells at so low a figure.

A prominent cause of scours in calves must be bacterial infection of the feed, from uncleanly milkers' hands, dirty feeding utensils, and even the ordinary atmospheric infection in transferring the milk from the udder to the calf's gullet. When the calf sucks, with the exception of the first draught, it gets little of this infected food; but when milk is carried to the creamery, it comes home infected to such a degree that if not sour when fed, it will soon become so in the warm cavity of the calf's stomach.

The books say that the first milk of the fresh cow is necessary for the welfare of the calf. I believe that this assertion is incorrect. That it is likely to be a mass of germs, and that it will irritate the alimentary tract of the calf is a fact. But that such action is necessary in the new born calf if not so apparent.

Nature does not always provide conditions that are ideally normal. Neither tonsils, vermiform appendix nor corns are beneficial or necessary to man; and I doubt if the colostrum of a cow is a benefit to a hand-fed calf. A vigorous calf running with the mother can withstand this evil as well as others, that the hand-fed, stable-housed calf would be well rid of.

If the calf has scours, let it take only a little fresh milk direct from the mother, and in only a few feeds in the twenty-four hours. Remove the cause and relieve the stomach and bowels as much as possible from labor in carrying out their functions. Give fresh, clean air to breath; but protect from dampness and cold draughts. In these cases prevention is much more valuable than cure.

The interesting question has been broached as to the susceptibility of the specialized dairy cow to tuberculosis. As my medical specialty has been diseases of the lungs and throat, I feel like giving an authoritative opinion in this matter. A cow whose surplus of nourishment goes to milk is no more subject to tuberculous infection than one whose surplus goes to beef and fat, always provided that general muscular exercise is equally taken in both instances.

A small well used pair of lungs, or any other tissue in the animal, is not so subject to tubercular diseased action, as is a large but under used part. The ability of any tissue to resist such invasion, depends upon its healthful state, the force of the blood current coursing through it, the completeness of its nourishment by a well balanced blood supply, the nervous energy directed to the parts, the thoroughness of the oxygenating process in the tissue, and the impure or imperfect air.

The cow with small lungs is not nearly so likely to become infected with tuberculosis while standing in the stable for the long winter season, as would be the cow with lungs larger than is necessary to oxydize its blood, or that could not be kept in a fine condition by heart action, quieted by resting. Athletes are almost sure to die of consumption if, after extraordinary development of their lungs by hard exercsie, they take to a sedentary life. Defects in breeding, lack of exercise and impure air have more to do with tendency to tuberculosis than anything else. Soft, delicate tissues are the breeding ground of the tubercular bacillus.

There seems to be considerable misunderstanding in the dual-purpose cow question, because of varieties in ideas as to the make up of that creature. It seems that Prof. Shaw does not advocate the dual-purpose cow for the dairy specialist. I certainly do not. Nor does anyone that I have heard express an opinion. But Prof. Shaw's papers confirm me in my opinion, that skillful breeding will produce a cow that will do fairly well for the family dairy, and yet will be saleable for beef when her best milking days are past.

It is probable that such cows would be uncertain when bred, in reproducing their all-round qualities, but there are such cows that would be probably more profitable for a certain class of general farmers to keep, than the straight dairy cow whose whole returns are in her milk.

The editor must not think that because, in my last article, I expressed my doubts as to its paying to buy concentrated foods for my cows, that my cows are not good ones. They are the best that I could buy in our region, and bring in about $50 a year on defective feed, most of which is the natural grass hay of the region, supplemented with a small addition of prepared proteids.

Further along, when we grow more clover and oats and ensilage, we will make a better showing. But it is a comforting thing to know that some of my cows will sell for $75 for beef at any time; while it is hard to have a cow that has been testing nearly 7% fat, fall to 3%, and then not be able to get a pound of flesh on her. I have such a cow, and cannot make up my mind to knock her in the head for manure.

If the oleomargarine men can be sat upon we may all give in complete adhesion to the special dairy cow; but if not, then the oleomargarine cow may be the cow of the future To whom do we send our dollars in the oleomargarine matter?

Official Tests of Holstein-Friesian Cows.

From June 1, to October 1, 1898.

ED. HOARD'S DAIRYMAN:—These butter tests are for seven consecutive days and are supervised by officers of agricultural colleges and state experiment stations or by persons vouched for by such officers. The amounts of butter-fat are determined by the Babcock test, and the amounts of butter are calculated on the basis of 80% fat to a pound of butter, the rule established at the World's Columbian Exposition:

Segis Clothilde Pietertje 44584; age 1 year, 8 months, 25 days; amount of butter fat, 7.629 lbs., amount of butter 9 lbs , 8 6 oz.

Clothilde Grace 41385; age 2 years, 3 months, 6 days; amount of butter fat, 9.339 lbs.; amount of butter, 11 lbs. 10.8 oz.

Aaggie Pietertje Clothilde 41384; age 2 years, 1 month, 17 days; amount of butter fat, 8.363 lbs.; amount of butter, 10 lbs. 7.3 oz.

Tehee Clothilde 41383; age 2 years, 1 month, 20 days; amount of butter fat 8.107 lbs; amount of butter, 10 lbs 2.2 oz.

Segis Aaggie Grace 39454; age 3 years, 6 days; amount of butter fat 11.811 lbs.; amount of butter, 14 lbs. 12.2 oz.

Segis Inka 36617; age 4 years, 6 months, 12 days; amount of butter fat, 14.803 lbs.; amount of butter 18 lbs. 8.1 oz.

Aaggie Grace Clothide 39452; age 3 years, 3 months, 17 days; amount of butter fat, 14.796 lbs.; amount of butter, 18 lbs. 7.9 oz.

Clothilde Artis Belle 2d 39861; age 3 years, 1 month; amount of butter-fat, 10.948 lbs.; amount of butter 13 lbs 11 oz.

Jannek Beauty's Inka Pietertje 28681; age 7 years, 1 day; butter fat 12.563 lbs.; amount of butter, 15 lbs. 11.3 oz.

Jannek Bright 2d, 22943; age 8 years, 10 days; amount of butter fat 14.430 lbs.; amount of butter, 18 lbs. 6.9 oz.

Aaggie Grace Boy's Topsey 22946; age 8 years, 13 days; amount of butter fat 13.800 lbs.; amount of butter 17 lbs. 4 oz.

Clothilde Artis Constance 39866; age 3 years, 20 days; amount of butter fat 11.423 lbs.; amount of butter 14 lbs. 4.5 oz.

Clothide Artis Aaggie Lass 39865; age 3 years, month, 1 day; amount of butter fat 10 824 lbs.; amount of butter 13 lbs. 8.5 oz.

Clothilde Artis Aaggie Bright 39864; age 3 years, 1 month, 22 days; amount of butter fat, 12.875 lbs; amount of butter, 16 lbs. 1.5 oz

Clothilde Lunde Artis 39867; age 2 years, 10 months, 28 days; amount of butter fat, 12 821 lbs.; amount of butter, 16 lbs. 0.4 oz

Homestead Girl's Shadeland Boon 40720; age 2 years, 1 day; amount of butter fat, 7.934 lbs ; amount of butter, 9 lbs. 14 7 oz.

Jetske Roe's Aaggie Artis 40718; age 1 year, 11 months, 27 days; amount of butter fat, 9.956 lbs : amount of butter. 12 lbs. 7.1 oz.

Dorothy Ondine Wayne 3d 38931; age 3 years, 4 months, 19 days; amount of butter fat, 11 820 lbs.; amount of butter, 14 lbs. 12.4 oz.

Aaggie Ideal's Black Beauty 36517; age 4 years, 4 months, 8 days; amount of butter fat, 13 338 lbs.; amount of butter, 16 lbs. 10.8 oz.

Beryl Wayne 32496; age 5 years, 8 months, 17 days; amount of butter fat, 12 930 lbs.; amount of butter, 16 lbs. 2 6 oz.

Aaggie Cornucopia 2d 30597; age 6 years, 2 months. 18 days; amount of butter fat, 15 830 lbs.; amount of butter, 19 lbs 12.6 oz.

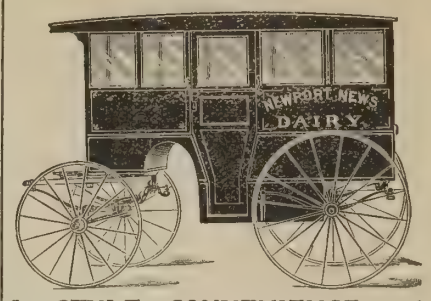
Vevie Night 2d 16002; age 9 years, 20 days; amount of butter fat, 14.666 lbs.; amount of butter 18 lbs. 5.3 oz.

Mage Clothilde 40929; age 1 year, 11 months, 24 days; amount of butter fat, 8.823 lbs.; amount of butter, 11 lbs. 0 5 oz.

Leah Veeman 4th 40264; age 3 years, 1 month, 24 days; amount of butter fat, 11.908 lbs.; amount of butter, 14 lbs. 14 2 oz.

Shadeland Amber 29330; age 7 years, 1 month, 18 days; amount of butter fat, 13.073 lbs.; amount of butter, 16 lbs. 5 5 oz.

Helena DeKol's DeKol 41976; age 2 years, 1 month, 6 days; amount of butter fat, 10.238 lbs.; amount of butter, 12 lbs. 12.8 oz.



Lena Bohn 2d 44349; age 2 years, 3 months, 9 days; amount of butter fat, 8.819 lbs.; amount of butter, 11 lbs. 0 4 oz.

Nickle Plate 42659; age 4 years, 6 months, 16 days; amount of butter fat, 13.418 lbs.; amount of butter, 16 lbs. 12 4 oz.

Elgin Belle 6th 46886; age 1 year, 9 months, 13 days; amount of butter fat, 10.417 lbs.; amount of butter, 13 lbs. 0 3 oz.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The aggregate offering of butter on Monday's Elgin Board of Trade was 12,060 pounds. Bidding opened at 16 cents and all sales were at that figure.

The market was declared steady at 16 cents.

The sales reported were:

Factory.	*Pounds.*	*Price.*
Evansville	1,500	16cts.
South Wayne	2,400	16cts.
Shattcck's Grove	2,460	16cts.
Malta	1,500	16cts.
Total	7,860	

The markets for the corresponding week of the three preceding years were as follows:

May 2, '98, 3,300 lbs. of butter sold at 16½ cts.
May 3, '97, 23,460 lbs of butter sold at 14@5 cts.
May 4. '96, 27,660 lbs. of butter sold at 15½ cts.

The New York market Monday was reported steady at 17 cents. H. C. B.

Elgin, Ill. May 1, '99

DAIRY MARKETS.

ELGIN, May 1—Butter—Market steady. Eight thousand pounds sold at 16c.

MILWAUKEE, Wis., May 1.—Butter—Creamery, fancy prints, per lb. 16c; extras per lb. 15½@16c; firsts per lb. 14@15c; seconds per lb. 12@13c; imitations per lb. 12@13c; dairy selections per lb. 12@13c; lines per lb. 10½@11c; roll, fair to choice, fresh 10@10½c. Market was dull and lower, with little trade. Receipts show signs of grass and the present make is not fit for storage purposes, wants being confined to consumptive requirements. Accumulations are liberal and receipts are 13 450 lbs.

Cheese—American full cream October Twins 11½@12c; New per lb. 10@10½; Brick, new per lb. 9½@10c; Limburger, fall, choice, per lb. 9@10c; winter made per lb. 8@9c; Swiss, Drum, choice 12½@13c; Block, choice, 10½@11c. Market declining for new; old steady; trade quiet.

Eggs—Fresh per doz 11c; cases returned. Market unchanged with receipts of 878 cases. Local wants are small and arrivals now have to be candled for storage purposes, and show more or less loss-off on account of the warm weather.

CHICAGO, Ill, May 1.—Butter—Creamery, extra, 16c; firsts creameries 14@15c; seconds 13@13¼c; dairies, selections 14c; extra ladles 12½c.

Eggs—Fresh, at mark, cases included, sold at 11½c.

Cheese—Full cream, Twins, new, good to choice 10½@11c; Young America 10¾@11c; Swiss 10½@13c; Limburger 8½@10c; Brick, new, 9c.

Cattle—Most grades of native beef cattle sold 10@15c lower, heavy grades showing the most decline. Some of the choicest light steers showed little if any decline. But cows and heifers were steady with undesirable stock and Texas cattle weak to 10c lower. Trade was active and comparatively few remained unsold. Of the 30,300 received at the four leading Western markets Chicago was credited with 22 000, about all of them being natives. Only seven loads of Texas were received. The best cattle on sale sold at $5 35 with the bulk of 1,150@1,450-lb. steers at $4.50@5. A week ago $5.60 was the top of the market Fed Western steers sold at $4 25@5.15; straight Texas steers 1,089 lbs $4.65; Mississippi steers 659 lbs. $3.85 and 1,056-lb oxen $3.55. Native cows sold principally at $3@3.75 and heifers $4@4.50.

Bran—Quiet and easier; sold at $11.50 per ton in bulk and $12.75 in sack.

Middlings—Quiet and sold at $12 per ton.

AVOCA, Wis., May 1.—Lone Rock and Muscoda Dairy Board to-day, offering 234 boxes; a few sold at 10 cents.

FOND DU LAC, Wis., May 1.—Offerings today 255 Twins and 210 Daisies. Twins sold for 10 cents.

PLYMOUTH, Wis., April 25—On to-day's board 20 boxes of Twins sold at 11¼c; 250 at 11⅜c; 55 at 11½c; 50 Young Americas at 11c.

BRILLION, Wis., April 21—The sales on the Brillion dairy board to-day were; 148 Daisies, 48 Twins, and 24 cases Young Americas at 10½c. Next meeting Friday, May 5.

SHEBOYGAN, Wis., April 26—Cheese—The sales reported today were: 200 Twins and Daisies at 11c, and 250 cases Young Americas at 11c.

SHEBOYGAN FALLS, Wis., April 26—Cheese—There were 374 boxes of cheese offered on the call board today, and all sold as follows: 150 boxes of Twins at 11¼c; 159 cases Young Americas at 11c; 55 at 11⅛c, and 55 at 11¼c.

HORTONVILLE, Wis., April 26—Cheese—Sales 85 Twins at 11c. The first meeting for the sale of cheese will be held May 4 at 10 o'clock a. m., and every two weeks thereafter during the season.

PHILADELPHIA, Pa., May 1—Butter—Solid-packed separator creamery, extra, 17½c; creamery firsts, 17c; creamery seconds, 16c; imitation creamery, extra, 16c; imitation creamery, firsts, 15c; imitation creamery seconds, 14c; ladle packed extra, 15c; ladle packed firsts, 14c; ladle-packed seconds, 13c. Print butter: Creamery extra, 20c; creamery firsts, 19c; creamery seconds, 18c.

Eggs—Pennsylvania and nearby, 13c; Western, 13½c; Southwestern, 13¼c; Southern, 12½c.

WASHINGTON, D. C., May 1—Market steady, extras, 17c; firsts, 16c.

ST. LOUIS, Mo., May 1—Butter—Weak; creamery, 13@18c: dairy, 12@16c.

Eggs—Steady, 10c.

KANSAS CITY, Mo., May 1—Butter—Steady; creamery, 13@17c; dairy, 14c.

Eggs—Receipts increasing; dealers beginning to buy on storage account; fresh Missouri and Kansas stock in new cases, cases included, 10½c; cases retured, 10c.

CINCINNATI, O., May 1—Butter—Quiet, 18c.

Cheese—Firm; good to prime Ohio Flat, 12c.

Eggs—Easier, lower, 11c.

NEWARK, N. J., May 1—Market steady, 17c for fancy creamery. Receipts liberal.

NEW ORLEANS, La., May 1—Butter—Easy, 17c.

NEW YORK, May 1—Butter—State full cream, large, colored or white fancy, 12c; choice, 11¼@11¾c; small fancy, 12½@12¾c.

Eggs—State, Pennsylvania and Western, 13@13¾c.

NEW YORK MARKET.

NEW YORK, April 29.—Butter—Receipts for the week, 34,403 packages. Exports for the week, 1,631 packages. The highest bid at Elgin was 15c; highest bid at Jamestown was 14½c, and the board at Elgin declared the market for a conventional business settlement basis to be 17c, the apparent idea there seeming to be to carry the Elgin market at about a par with New York prices and make Elgin a central distributing point. Receipts at New York are comparatively less than normal for this time of year, but the demand seems lighter and there is a general cutting of prices among retailers; today (Saturday) placards in many retail grocers' windows read "Extra Creamery butter 16c per pound."

Extra creamery has been quoted at 17c all through the week; at the close, however, there is more butter than buyers and lines of fine stock are offered at 16c. New York State dairy in very light supply and wanted if quality is fancy; Fresh imitation and ladle goods are arriving very sparingly and are of poor quality and sell for bakers' use at 13@13½c. Exporters would pay say 14c for fine ladle goods, but there are none here. We quote: Creamery, extra 17c; medium, 15½@16c; poor, 14@15c. Dairy, extra, 16@16½c; medium, 14@15c; poor, 12@13c.

Cheese—Receipts for the week, 11,520 boxes. Exports for the week, 3,885 boxes. The export trade is moving into Canada. The three leading exporters of cheese to the United Kingdom leave this market this spring and station themselves in Montreal.

Genial were these gentlemen and courteous—kindly and useful were they, and their going makes the frigidity of a vacuum in commercial circles and marks the loss of a business which at its flood brought to American dairymen an increment of $14,000,000 per annum

The market has ruled soft and easy all the week. Holders of the remnant of old stock like to close it out and the bulk of new makes arriving were sold Monday at 10c, Tuesday and Wednesday 9¾c and closes drooping at 9½c. We quote: Old cheese, extra, 10½@11c; medium, 8@9c; poor, 5@7c. New cheese, extra, 9½@9¾c; medium, 8@8½c; poor, 5@7c.

Eggs—Receipts for the week, 71,837 cases. We quote: New York & Pennsylvania, per doz., 14@14½c; Western & Northern, 13½@13¾c.

DAVID W. LEWIS & Co.

117 Chambers St.

BOSTON, Mass., May 1—Butter—Market steady, 17c.

Cheese—New cheese quiet at 11c.

Eggs—unsettled, 13@14c.

BALTIMORE, Md., May 1—Butter—Market quiet; creamery, separator extra, 20@21c; extra, first, 20c; creamery, first, 19c; ladle extra, 14@15c; Western store-packed, 11@13c

Eggs—Market steady; strictly fresh stock, 12@12½c.

BALTIMORE MARKET.

BALTIMORE, Md., April 27—Butter—The receipts of separator creamery this week have been of about the usual quantity at this season, but as they have had to bear the burden of the bulk of the demand for all table grades, they gave out, in first hands before all the orders for the week were filled; it is quite likely that the greatly reduced prices has had something to do with increasing the run on this variety. Gathered cream makes have been very scarce, the receipts not half satisfying the regular trade, so jobbers have had to supplement their supply with purchases from northern cities. Imitation creameries are in very light receipt and good demand; choice makes are bringing about the same prices as corresponding grades of gathered cream products, and some buyers prefer them. Ladle packed butter is unusually scarce, and the falling off in the receipts makes a material reduction in the volume of business done by the receivers, when the present sales are compared with the work of previous years. There is very little roll arriving, and that little is eagerly sought after by the market house cutters at full prices. Blocks and prints are in fair receipt, but the demand still is in excess of the supply.

Creamery Separator, extras 19c; firsts 18c; seconds 17c. Gathered Cream, extras 18c; firsts 17c; seconds 16@17c. Ohio, extras 18c; firsts 17c; seconds 16@17c. Iowa & N. W. Ladle, extras 16c; firsts 13@14c; seconds 12c. Ohio & Indiana Ladle extras 14@15c; firsts 14c; seconds 13c. Roll, extras 14@15c; firsts 13@14c; seconds 12@13c. W. Va. Roll, extras 13@14c; firsts 12c; seconds 11@12c. Creamery Blocks (2 lbs.), extras 22c; firsts 21c; seconds 19c. Creamery Prints (¼ lb) extras 23c; firsts 20c; seconds 18c. Md., Va. & Penn. Prints, extras 20c; firsts 18c; seconds 15@16c.

Eggs—So far this week the receipts have been fairly liberal; there has been a good steady demand, and receivers have been enabled to keep all receipts well cleaned up from day to day; our market, though somewhat lower than it was last week, is still in good shape at 12¼ cents, and we advise liberal shipments of choice eggs.

NOTE—If possible to get crates; we would advise you to do so, as the stock arrives in much better condition and will sell to better advantage than eggs packed in barrels or boxes; try crates and see the good results.

Western Md. & Penn., per doz., 12½c; Eastern Shore (Md. & Va.) 12½c; Virginia, 12½c; Western & W. Va, 12½c; Southern, 12c; Duck eggs, 12c; Goose eggs, 16@18c.

Cheese—Receipts light; demand good; market steady.

N. Y. State, Cheddars, fine 12@12½c; choice 11@11¼c; fair 9@10c. Flats, fine 12@12½c; choice 11¼@11¾c; fair 9@9½c. Small, fine 12¼@12¾c; choice 12@12½c; fair, 9½@10c. Ohio Flats, fine 11@11¼c; choice 10½@11c, fair 8½@9c Picnic, fine 11½@12c; choice 10@11c: fair 9½@10c. Swiss cheese, fine 11@12c; choice 10c; fair 8½@9c.

301 Exchange Place. G. M. LAMB & BRO.

Latest quotations for fancy creamery—Buffalo, 16@16½c; St. Paul, 16c; Minneapolis, 16@16½c.

LIVERPOOL, May 1—Butter—Finest United States, 84s; good, 65s.

Cheese—American finest white and colored, 51s 6d.

FOREIGN MARKET.

BOSTON, April 29, 1899—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane, give butter markets as dull and declining, owing to increased receipts of Danish and other Continental butters. The Irish and home make is also increasing, and on top grades there has been a decline of 1@1½c during the week. Australian is about cleared up. Some stray lots of American creamery are selling from 16@18c. Ladles have sold moderately well when they are offered from 15 cents downwards.

Cheese markets are all the turn easier. The conservative action of buyers prevents holders controlling the market and prices have given way ¼c during the week on finest Septembers, which are to be had at 11@11¼c. Under price cheese is in light supply with a very little to be had below 10½c.

MANCHESTER, England—Dowdall Bros. special report of April 22nd says: The weather is very cold at nights, sometimes even frosty, but in day-time it is clear and spring-like. Vegetation is making almost no progress. Such are our reports from most of the butter producing countries Landed prices have been below shipping rates for Danish and Swedish. Copenhagen has in consequence reduced the official quotation 4 kroner, in order to get more in line with the price of consignments. Demand is steady, and as retailers are selling with little or no margin at present, consumption will be large, and will help to clear off supplies rapidly. Prices are now about in line with the corresponding period of last year, and as favorable for this period of the season as we can reasonably expect. Supplies are still extremely small from Ireland. Advance parcels of some of the best creameries show excellent quality. Cork market has officially opened for the new season. Firsts are realizing good prices, quite comparable with Danish quotations. Shipments at sea of Danish and Swedish butters for next week's North of England markets are 21,677, and Finnish, 3,893 casks. In margarines and mixtures a fair steady trade is doing. Arrivals are via Hull, 11,694 packages, and via Grimsby, 6,133 packages.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—"Reta's Parole," 20 months' old, solid color, and standard bred. Fine individual and well behaved. Direct blood of best St. Lamberts and Combination. F. L. GASTON, Normal, Ill. 12-tf

Situation Wanted as general farm manager, by man of practical knowledge of business and all its branches of farming and stock raising. First-class testimonials from last employer. Address "MANAGER," care Hoard's Dairyman. 12-2

Wanted—A first-class man to rent a fine dairy and stock farm within three miles of the city of Janesville, Wis. H. F. KELLER, 251 South Jackson St. Janesville, Wis. 12-4

A good man is wanted, right off, by the MT. PLEASANT CREAMERY CO. at Mt. Pleasant, Pa. One who can make first-class ice-cream in all styles and fine butter. Address immediately. 12-2

For Sale—Holstein-Friesian bulls one year old and over of choice breeding, sired by a Mercedes bull. Also eggs from high scoring B. P. Rocks. I. L. CURTIS, Poynette, Wis. 12 2

Apply to agents Chicago & North-Western R'y. 12-2

—THE—

SEPARATOR QUESTION.

Do you want a second or third class separator, of less than claimed capacity, requiring high speed and heavy power, of second or third class mechanical construction, and doing second or third class work?

Or do you want a first class separator, of actually greater than claimed capacity, requiring low speed and light power, of the very best and most careful mechanical construction, and capable of thoroughly first class work under the widest range of operative conditions?

You can find the former in some half-dozen makes of separators, more or less advertised, and showing fairly well "on paper."

You can find the latter only in an "Alpha-De Laval" Disc System machine, which in every feature of centrifugal separation efficiency stands in a class by itself.

Meeting of Farmers' Institute Workers and Directors, at Rochester, N. Y.

ED. HOARD'S DAIRYMAN:—The third annual meeting of this association was held in the assembly rooms of the New Osborn House, Rochester, March 29-30. The Hon. Franklin Dye, New Jersey's institute director and president of the association, presiding. Vice-President, F. E. Dawley, of Fayetteville, N. Y., and F. W. Taylor, Lincoln, Nebraska, secretary and treasurer, were also present.

The states represented at the sessions and banquet were New York, New Jersey, Ohio, Michigan, Wisconsin and Nebraska, while Canada sent Mr. James Sheppard, of Queenstown, Ontario. Besides the foregoing named gentlemen, there were present John Gould and T. B. Terry, of Ohio; Geo. McKerrow, of Wisconsin; Kenyon L. Butterfield, of Michigan; and the following from New York: H. W. Collingwood, Prof. S. A. Beach, Edward VanAlstyne, Prof. I. P. Roberts, A. R. Eastman, Prof. V. H. Lowe, F. A. Converse, James E. Rice, George T. Powell Prof. Geo. W. Cavanaugh, Dr. C. D. Smead, J. P. Clark, P. J. Cogswell, George W. Sisson, Jr., W. T. Hughes, G. A Smith, W. W. Hall, V. C. Beebe, Henry VanDreser, W. W. Smallwood, A. L. Twitchel, C. E. Chapman, Ellis Woodworth, C. W. Jennings.

The first number of the program was the opening address by President Dye. It was followed by a paper having for a heading: "Fifteen Years in Institute Work in the United States," by T. B. Terry. This was in many ways one of the most interesting papers read, although it was not of a make up to bring out discussion, being of an historical character. He said that the institute began in a small way in Ohio. At first the speakers received no pay and boarded themselves besides. Ofttimes they even built the fires in the halls, then went out and invited people to come in.

Sometimes a boy was hired to go about the streets and ring a bell as they sometimes do to call the people's attention to an auction. At one place, where the institute was to be held in a court house, the sheriff called the meeting from the doorsteps. Often the audiences were very small, numbering not more than a half dozen; and, at one time, he met but two, a man and his wife, who said they had driven six miles to hear his lecture on "The Wife's Share." When they told him that, he got up and gave it to them *verbatim et literatim*, taking an hour and a quarter in which to do it. He had not another listener. Now-a-days, there has come a change, and not only the farmers and their families, but the village people as well come out in force. He, not long since attended an institute at church, which, when he arrived was so crowded that he had to crawl through an open window, while the crowd outside was so large that the windows of the church had to be opened so that the speakers could be heard by those who could not get in.

Concluding his bit of history, Mr. Terry offered some suggestions as to how best to continue institute work. First, secure a hall and decide on how it shall be paid for, but don't take collections for it at the institute. He had seen three trials before enough was secured, then a few had to bear the brunt. They may as well do it before as after the institute.

He also favored a fall meeting of speakers with the conductors and directors of several states, to formulate plans for the winter's work, so that all could work in harmony, and each would know his part. Small places he considered best; small meetings, scattered over a county, with a small force of speakers, are better than large ones.

We must take instructors to the farmers; they can't or will not, go far from home. The director should get a good local correspondent in each place, one who can and will "push things" and thoroughly advertise the meetings. Secure rooms near the hall, so that the speaker can be well cared for.

Numbers do not always count most. Many times small audiences are better than large ones. The work should be made educational. As a rule, the average farmer is not informed. Many of them know nothing, scarcely, of the value of manure, and so allow their liquid voidings to go to waste. This subject he considered the most vital to-day, connected with institute work. The farmers *must* be awakened to this fact.

The institutes not only must be progressive, but must be conducted so as to reach all classes of farmers. They will no longer be popular unless they are. The object of only giving general instruction or information, is not enough.

We must have, not only better farms, but better homes.

Mr. Powell—The farmers' institutes have made wonderful progress since I was director, six years ago. We are educating the farmers, and have been all these years, and the instructors must keep ahead of the people, else the institute will fail. The question is, can they do this? The institute speakers are working and studying hard, and the experiment stations are giving much information, hitherto furnished by the institute, so that now the duties of the institute worker are more onerous than ever before. He must, therefore, not only be a student, but a worker also, striving to keep abreast of the people. The day he fails in this, that day the influence of the institute will be forever gone.

Mr. Eastman—I am not an institute director, but have done some work as a speaker at institutes, and I am going to endorse much which Mr. Terry has said, and proposed. Old workers appreciate this advice more than do young ones, and I am satisfied that small towns are best for institutes. Too many in the large places make an institute a sort of entertainment. They don't care so much for what is said, as they do for something new, by way of entertainment. Select small places, and have a less number of speakers, which means less expense. But eliminate the "lap-overs." The speakers of the first day are gone, when those of the second day arrive. None of them know anything of the addresses or questions of the first day, and the new comers cannot, many times, answer the questions in the box that a former address brought out. Substitute one day meetings for these lap-overs. No speaker can become acquainted with an audience at one session.

Mr. McKerrow—We hold lap-overs; two men and a conductor, however, are always left.

Mr. Eastman—That will do in your case, because two or three men remain behind; while with us, all of the first day go on to the next meeting, leaving the new comers to finish up the institute.

Dr. Jordan in his paper, among other reforms, suggested the eliminating of local speakers from the institute, as a rule.

Mr. Van Alstyne—I am heartily in favor of Dr. Jordan's proposition to eliminate these speakers. Leave them off the program. I have seen the work of the entire institute corps of speakers at an institute, neutralized by the contradictory remarks of one of these speakers.

Mr. McKerrow said he was in favor of employing the man who is capable, whether as local or state speaker. But he must be competent, honest, and one who stands well at home, pays his debts, and is able to keep ahead of the procession of farmers.

Mr. McKerrow suggested that small exhibits of farm products be encouraged and small prizes offered for the best of them. These will interest the farmers, and those of them who have pretty good things will bring them out. The business men—merchants, as a rule—in his state, offer the prizes. It has worked well so far in every place. The only trouble being some of the men would stay in the rooms where the exhibits were displayed, thus neglecting the institute; but, as a rule, more farmers come to the institutes where these prize exhibitions were made, than otherwise. "In some places the exhibits have grown so large that they have come to be an elephant on our hands, while, in others, they have been the means of building up a first-class institute each year."

At some institutes there are live stock exhibits for which prizes are offered, the judges of which are forced to give their reasons for the awards as made, right on the spot. This fills the large tent with men and women, who are anxious to hear the "whys and wherefores" of the judges.

The speaker said that he favored these exhibitions and awards; also short papers and addresses, but long discussions. The farmers know better than we do what they want and they like discussions better than long talks or papers. But he did not favor the holding of a farmers' institute in connection with a regular fair, unless some extra inducement can be offered to hold the crowd. An ordinary farmers' institute on a fair ground is a "flat failure;" but an exhibition of farm products at an institute tends to elevate it, and is sure to bring out a larger attendence, especially when these prizes are offered by the merchants. They talk with the farmers, read the programs to them and urge them to come out, thus advertising it more generously. Sometimes small prizes are offered for the best ten minute essay to be read by a farmer's son or daughter, and as a rule, where large exhibits are made, the hall is closed during the institute hours, and at some places, large, genuine shows of poultry, horses, and sheep are made. At Fort Atkinson, it was dairy cows, while 100 horses were shown at another institute, elsewhere.

Mr. McKerrow's address was very instructive and brought out considerable discussion.

Belleville, N. Y. C. W. JENNINGS.

Large Overrun of Butter.

ED. HOARD'S DAIRYMAN:—I am a young and inexperienced farmer and dairyman, having been engaged in the business less than one year. My milk is made up at a creamery which manufactures at a fixed price per pound, and pays according to butter fat, etc. I understand that the excess of butter over fat in a given amount of milk is held to be about 15% to 16%, while the statements I receive from the factory vary in the excess all the way from 14½% to 25%. From May 1898 to the present the excess figures as follows: May 22¼ %, June 17.9 %, July 14¾ %, August 14½%, September 16%, October 19%, November 25%, December 20%, January 24%, February 26¼ %

Now, if you will explain to me why when 15% to 16% is held to be about right, ours should reach such figures as indicated above I'll certainly be grateful to you.

N. Y. SUBSCRIBER.

The average overrun, as stated before is about 15%, but it may be more or less according to the accuracy of testing, exhaustiveness of separating and churning, and the physical condition of the milk. All these conditions affect the overrun. Variation in the above conditions will frequently cause a deviation of several per cent, either above or below the average. In the above case where the February overrun is 11.25% above the average, and others almost as high above the average, we should suspect the accuracy of the testing. Factory work should not show such extremes if the work is performed in the proper manner. The use of weak acid would bring the test so low that large losses could be made by the separator and churn and yet show an excessive overrun.

If the testing is accurate, then there may be an excess of water in the butter, a condition which can be easily obtained by chilling the butter before working.

Feeding Corn Fodder.

The Advantages of a Silo.

ED. HOARD'S DAIRYMAN:—Enclosed I hand you $1 in cash for renewal of my subscription to HOAED'S DAIRYMAN for the coming year.

I should like to get your opinion through the columns of HOARD'S DAIRYMAN of my method of feeding fodder corn:

1st. Stock is from twelve to sixteen head

TESTED BY THE MILK PAIL

Quaker Dairy Feed

is made entirely of grain—principally of oats—combined in scientific proportions. It is complete for the production of milk and the proper maintenance of the animal.

Sold only in sealed and branded sacks.

Trouble Cows off feed, couple of cases of caked bag and a cow or so with milk fever! Care and watchfulness are great preventives, but feed is far more important. No such cases follow the use of our feed. Common sense and Quaker Dairy Feed are the watchwords. Enquire about it; you will find we are right.

"MODERN DAIRY FEEDING"

An invaluable book containing scientifically proportioned rations, including every form of roughage and every variety of feed. Sent postpaid on request. Address Science Dept.,

Eureka Harness Oil is the best preservative of new leather and the best renovator of old leather. It oils, softens, blackens and protects. Use

Eureka Harness Oil

on your best harness, your old harness, and your carriage top, and they will not only look better but wear longer. Sold everywhere in cans—all sizes from half pints to five gallons.

Made by STANDARD OIL CO.

Parted In A Dream—(New) Pronounced by critics a beautiful song. Very popular. Founded on strange incident of Cuban war. Regular price, 50c. Sent to our readers for 25 cts., post-paid, including also miniature page of DARLING LENORE and MOTHER'S DARLING YET.

Darling Lenore—(New) Is called a very catchy, pretty song with beautiful flowing melody, all in waltz time. Becoming very popular. Regular price 50 cts. Sent post-paid to our readers for 25 cts. with a miniature page of PARTED IN A DREAM and MOTHER'S DARLING YET.

Mother's Darling Yet—(New) Pronouuced very pretty. Is extremely popular with singers of lullaby songs. Regular price 50 cts. Sent post-paid for 25 cts., and with it a miniature page of PARTED IN A DREAM and DARLING LENORE.

For 2 cts. I will send one miniature page of each of the three songs. Address the author,

HALBERT L. HOARD, Fort Atkinson, Wis.

of cattle, mostly of Ayrshire and Durham grades.

2nd. I raise each year from two to three acres of fodder corn, which usually gives a very heavy crop.

3rd. Corn is cut before frost and stored under an open shed in such a way as to allow the air to freely circulate through it. As wanted for feed, corn is cut about one inch long by horse power and fed as follows: The feed for morning is placed in a water tight box and enough boiled water is added to cause it to steam up quite freely; we then cover the box up carefully and allow it to steam all night. It is usually warm in the morning, when it is fed, after adding whatever grain we are feeding. The same process is followed in the morning, for the evening meal.

4th. What advantage would a silo be over my present method of feeding corn? I might say that I vary the above feed to some extent by feeding clover hay instead of corn, but prepare it in the same way. I have never had a cow refuse to eat a liberal allowance, and a sick animal is an exception.

I might add that my farm of about sixty acres is some fifty miles from Montreal, and I have to depend entirely on some one else to attend to it. A SUBSCRIBER.

Montreal, P. Q.

It would be difficult to enumerate all the advantages of the silo. Some of them, briefly stated, are as follows:

There is no way in which storage can be provided for fodder corn at so little expense and take up so little space as in the silo.

There is no way in which a field of corn can be harvested with so much expedition as to put it into a silo.

Although it has been demonstrated that, under the most favorable conditions and with the greatest care exercised, the actual loss in nutritive elements is about equal in field curing of corn and in a silo, yet it is so difficult sometimes to command these favorable conditions and to insure this degree of care that the silo comes in somewhat in the way of insurance against bad weather and lack of proper care.

Another advantage of the silo is that it enables the farmer to make one job of putting his corn fodder into the best possible condition for feeding, so that no matter what demands may be made upon his time from day to day through the winter, this feed for his cows is always ready to his hand.

Having said this much, it is eminently proper for us to add that Subscriber's method of feeding his fodder corn corresponds in effect with the directions we have so often given in the DAIRYMAN for feeding corn stover. When we have stover to feed, we like to run enough through the cutter to last for three or four days or longer, and if it is not already damp enough, to add a little water so that when lying in the pile it will heat and soften up very materially, making, as one might say, silage in a degree.

What to Grow for Silage.

ED. HOARD'S DAIRYMAN:—There is one point put forth by the various authorities on silage that does not seem consistent with my views. Protein is the most expensive feed with us, as we raise hay in abundance—such as timothy, red top and the various clovers—which gives us all the organic matter and carbohydrates we require.

Now you say that peas and oats contain 25% more protein than corn. By the evidence of the various statements in the DAIRYMAN, they all agree that as much oats and peas can be grown per acre as corn. Why then should we grow corn in preference to oats and peas? I make this inquiry for the benefit of the farmers of this state. I know of one farmer in this section that filled two silos, one with corn and the other with oats and peas. He fed the oats and peas first; when he fed his corn, it took two quarts more of grain to keep his cows up to the same flow of milk that the oats and peas gave. Will you kindly enlighten us upon the point in question? H. F. G.

Kenduskeag, Maine.

Conditions in Maine may be different from those in Ohio, Wisconsin, Texas and various other states. Ordinarily it is not advisable for the dairy farmer to raise over much timothy and red-top hay. He can put his land to more profitable use. If one can raise more oats and peas, per acre, than of corn, let the area to corn be restricted. In other words, let the main dependence be put upon the crop that will produce the most feed at the least expenditure for labor and land.

Practical Suggestions in Dairy and Creamery Managment.

From the twelth annual report of the Iowa dairy commissioner:

It is a good thing to know how to do, but it is a far better thing to do as well as we know.

Each dairyman should strive to produce the best and sweetest of milk, and then see to it himself that it is delivered to the factory in the best possible condition.

Own and milk good cows. If you have poor ones send them to the butcher.

Never use or sell milk from diseased or unhealthy cows. It is dangerous even to feed it to the pigs.

Keep the cow warm and dry.

Feed clean, bright food in variety to produce good results.

Do not allow a cow to drink water you would not drink yourself.

Keep the cow clean by using plenty of clean, bright bedding.

Milk with clean, dry hands as quickly as possible.

Strain milk through cloth, thick enough to retain any particles of dust or litter that may be in it.

It takes as much muscle to milk one hard milking cow as it does to milk four or five easy milkers. Sell her.

Treat cows quietly and kindly; excitement affects the quantity and quality of milk.

Remember when filling cans with skimmed milk at the creamery, that it is not always the other fellow that needs watching.

The cornstalk, either shredded or in ensilage, is one of the best feeds for the cow. Hundreds of thousands of dollars' worth of this feed are annually lost in Iowa.

In freezing weather, scald can covers just before starting the milk for the creamery. The cream will not stick and freeze in them. Also cover cans.—*Gazette*, Sumner, Ia.

Gentlemen

The Gluten Feed finally got here; It arrived here the 16th, was glad to get it for our cows were failing in their milk every day. They have gained in the last four days to twenty five gallons more per day than they were while we was out of the Gluten Feed.

We think Gluten Feed is second to none as a milk producing feed, it makes more milk and better milk than any other feed we can get.

Yours Respectfully
John Shugart & Son.

What We Claim
for the
REID Long Spindle
SEPARATOR

Our new Long Spindle Separator and Belt Tightener, when taken together, will run with one-half the power required to operate our old style machine, *and less than half the power required to run any imitating separator.*

It requires practically no oil, the top bearing being frictionless. It requires no special foundation.

There is less wear and tear on the belts and the bowl will keep in perfect balance always.

Our improvement consists in lengthening the spindle and putting the upper bearing above the bowl so that the bowl is carried between the bearings; thus, we reduce the friction to a minimum and consequently the amount of power required.

Our new **BELT TIGHTENER** is calculated to take up all tension in the bowl automatically and consequently operators have no trouble in keeping the machine up to full speed, as the bowl cannot slip.

There Tighteners may be applied to any of the Reid Improved Jacks or the old Danish Weston Jacks.

Mr. Wheaton's Canadian Dairy Notes.

Marketing Cheese.—Dairy Legislation.—Speculating in Cheese.—Agricultural Exhibitions.—Spring Cheese.—Dairying in England.

ED. HOARD'S DAIRYMAN:—A very important part of the business of cheese making in this country from a factoryman's or patron's point of view, is the selling of the product. For this purpose a number of cheese markets or local dairy boards of trade have been formed (about 20 in Ontario) where the salesmen of the factories meet the buyers and offer their goods for sale, by auction or by what is known as the "Call" system.

This system has been in operation in some form or other almost since the first factory was built, and in many ways has been a lasting benefit to the country and to the dairymen. But the best of systems often have their weak points, and one of the weak points in the system in question has been that none of the rules or regulations adapted by the various boards could be properly enforced. This weakness in some ways has made the operations of the markets a kind of "farce". Rules and regulations governing the operations of the board have been adopted by each one at the opening of the season, only to be broken by a member at the very first opportunity offered to make capital out of doing so.

One of the rules common to every board is that no member shall buy or sell cheese on the regular day for the market, excepting on the market, and according to the plan adopted.

It has been found very difficult to make members obey this regulation to the letter, though by keeping at it during the whole season would give better results to the factorymen.

Another grievance and complaint has been that very often cheese is sold subject to inspection, and rejected by the buyer, when he has not sufficient cause for so doing. There have been more complaints on the part of the dairymen in this particular, during last year than ever before, and it was felt that something would have to be done to remedy matters.

The remedy has come this year in the way of legislation passed at the session of the Ontario Parliament recently prorogued, which provides for the incorporation of these local dairy boards of trade and the appointment of competent inspectors to decide disputes between factorymen and buyers in cases where cheese is bought and rejected.

It may be claimed by some in the trade that this law is not workable and that the person who buys the goods has the right to reject them if he does not consider them first class and according to terms of sale. While this may be the case, it is also true that frequently cheese are rejected after being bought on the market, subject to inspection, when there is no other cause for doing so than that prices have dropped a little in the meantime.

This rejection of purchased goods would not have such evil consequences if the loss sustained by such actions fell upon the patrons. But in the majority of cases it falls upon the maker, who is less prepared than anyone else in the business to stand it.

The almost universal practice here, when a maker is engaged to make cheese, is to hold him responsible for the quality of the goods turned out. In cases where cheese is rejected and a loss is sustained, the maker has to foot the bill. If the goods are really superior and their poor quality is due to the maker's lack of skill or neglect, he certainly should be held responsible for the loss. But where cheese is rejected upon a whim of the buyer, who finds some trifling fault with it, it is nothing less than robbery to make the maker pay for it.

We have heard of several cases of this kind during the past year or two, which we sincerely hope are not as bad as painted, where cheese were bought on the market and at first rejected but afterwards taken by the buyer at a lower figure, the maker paying him the difference as a kind of "hush" money.

One may ask, "Why does the maker agree to do such a thing?" The position of affairs is just this: The maker has a reputation to guard, and if he allows the report to get abroad, that his cheese has been rejected, whether it is up to the mark or not, his position as a first-class maker is injured both among the patrons of his own factory and among other factories.

The Cheese and Butter Makers' Association, formed over a year ago and composed entirely of makers, is doing considerable to counteract this tendency of some of the buyers and to protect makers, who are not in a position to stand up for themselves. If every maker however would stand right out and when a buyer makes a demand like the one referred to, would refuse to let him have the cheese at any price we hardly think there would be much rejected that was of good quality.

No one in the trade expects a buyer to take goods that are not up to the mark. But there are two parties to every transaction of this kind and if goods are rejected the owner or the factory's representative should have the right to have them inspected by a competent, independent third party whose judgment should be final. Such provision is made by the law recently enacted. As to how it will operate in practice we will have more to say later on. The very fact that such an individual is recognized by the law of the land may serve as a deterrent, and we may not hear of the unsavory transactions so frequently reported during the past year or two.

Another piece of dairy legislation is on the tapis at Ottawa, where the Federal Parliament is in session. This is a bill to prevent the buying and selling of goods that are not made nor in prospect of making, or in other words, to prevent what is known as selling "short". This matter was before the Dominion Parliament a year ago, but was withdrawn in order to obtain the views of the dairymen of the country as to the need and wisdom of such legislation. Quite a number of replies to a circular sent out have been received, the majority of them being in favor of such legislation being enacted.

Looking at the question in a somewhat narrow way, and from the standpoint of certain transactions occasionally transpiring, in which the price of cheese has been advanced through "short" selling, one must come to the conclusion that such a practice is a good thing for our dairymen.

But if we take the broader and wider view and consider the industry as a whole and its operation from year to year, no other conclusion can be come to than that the "short" selling of cheese is not in the best interests of our dairymen, and, in fact, is a positive detriment.

A person who sells, or offers for sale, cheese or other goods which he has not in his possession, does so with the hope of getting them at a price that will enable him to make a good price out of the transaction. From the moment his bargain is made with the English dealer, or anyone else, all his efforts will be directed towards bearing the market down as low as possible so that he may be able to buy at a good profit. And though there be a temporary rise in prices, when "short" selling negotiations are being made, so soon as the bargain is made, strenuous efforts are at once put forth to bring about a depression in the market.

Where there are several transactions of this kind made, and there are several persons in the trade endeavoring to depress the market, such depression is sure to follow to the lasting injury of the producer.

We are inclined to the view, therefore, that if a law to prevent this practice is passed, and it can be properly enforced, it will place our export cheese trade on a better working basis. What the average dairyman in this country wants is to be able to do business on a fair basis. But this cannot be done if there are individuals in the way ready to manipulate the market and turn as large a share of the profits as possible their own way. If this manipulation can be prevented by law, or otherwise, and the business be allowed to regulate itself in accordance with the supply and demand, there is good reason to believe that our dairymen would fare a good deal better one season with another. At any rate, they would have a better idea of where they were at as regards market conditions and could govern themselves accordingly.

Just now the leading fairs and exhibitions are making preparation for their fall shows. No especially new features have been provided for in connection with the dairy display, with one exception. The Toronto Industrial fair, which, without exception, is the best all round annual agricultural show held on this continent, is making a new departure, and will hold next fall a butter-making contest.

As far as we know, this is the first time that such a contest has taken place on this side of the Atlantic. At any annual exhibition or fair, butter-making contests form a most attractive feature at many British shows, and are exceedingly popular among dairymen. It is the intention of the management here to make this the important feature of the dairy branch of the show this fall. Though the prize list and rules of the contest have not been given to the public, yet we understand that it is the intention to make the competition open to butter makers either in Canada or the United States.

Quite a number of factories are now well under way, making early spring cheese. It is expected that fodder goods will be made till well on to the middle of May, owing to the backwardness of the spring. Though there were big crops of hay all over this country last year, a scarcity of feed is reported in some sections, chiefly in Western Ontario. The supply of fodder goods will therefore be larger than usual.

Prices are well maintained and a number of factories last week (April 23rd) sold their April output for 10 cents and over. Better attention is being given to curing the product this season and therefore it is claimed that the quality is ahead of other years.

Old cheese is quoted in Montreal at about 11 cents, but there is very little to be had. The total decrease in shipments from Montreal and New York from May 1st, 1898, to date is 545,016 boxes as compared with a year ago. The shortage from Canada of about 230,000 boxes is the largest in the history of the trade, which makes the outlook for 1899 very bright.

According to reliable reports a change seems to be coming over the methods of dairying practiced in Great Britain. The large supplies of butter from outside have caused many of the English dairymen to turn their attention towards supplying milk to the large cities, instead of making butter. This is causing a falling off in the home supply of butter and leaving more room for foreign goods, and Canada will likely come in for a large share of the trade. At no time during the past twelve months have the English markets been surfeited with surplus butter as in former seasons, though the ship-

ments from this country have been greater.

Prices for creamery have got down to an export basis which has enabled more business to be done on English account. Sales were made last week at Montreal at 17@17½ cents with a steadier feeling reported. Sales are reported at the factories at as low as 16@16½ cents per pound, which is 3 or 4 cents lower than when we last reported.

Toronto, Canada. J. W. WHEATON.

DAIRY HUMOR.

The DAIRYMAN is a pretty sober paper, for it has to deal with hard facts all the time. But its correspondents often give off a flash of keen wit and humor, which we feel it would be a loss not to record.

The other day, in response to our offer of a 25 cent trial subscription, we received the following keen reply:

ED. HOARD'S DAIRYMAN:—Somebody did not know me when they gave you my name as an enterprising fellow. The truth is I am too lazy to deny it, and so send along the 25 cents to save further annoyance (to you). I am a Jersey crank and know nothing else, scarcely. Have a son of Recorder (of your state) and "Tivoli", a St. Lambert bull at the head of my herd. I presume your columns are open to advertise good Jerseys; I really think the "Governor" down in his big heart rather likes them. I see by the *Jersey Bulletin* (conducted by an expert chicken man) that your paper sometimes makes bad breaks, but never mind, don't be discouraged; when you get this quarter, use it to increase your store of knowledge where Col. J. thinks you are lacking.

It certainly don't cost much to be informed for he (the chicken man) soon got so smart that he could believe anything he heard in favor of his pets.

Now for five months do your best for Ohio. J. A. P.

We hasten to assure our Ohio friend that his 25 cents shall be faithfully expended in the direction he desires, and with increased faith, since he has shown how easy it is to know all about the cow.

Experience With Ensilage.

Its Value in the Dairy.

ED. HOARD'S DAIRYMAN:—I have been much interested in whatever has appeared, from time to time, in your excellent journal, in relation to silos and ensilage, as in this way valuable suggestions are continually being made as the the results of experience, that should be of great help to those engaged in dairying. I here contribute a little from my own experience, hoping it may be of interest to others.

For many years we have raised fodder corn, as we term it, that is, corn to feed green to the cows until frost comes, and the larger part to cure and keep for winter use.

For this purpose a variety well adapted for this climate, known as the Sanford corn, and now largely grown in New England for the silo, is used. It is grown the same as if it were to be husked, only a little thicker, and with suitable cultivation a large amount of fodder, per acre can be secured, and at comparatively small cost. The crop well cured, makes excellent feed for the cows in late fall and winter, producing good results in milk and butter.

But where a large amount is raised, there is much labor and trouble in curing and properly storing it for use. Only in a very favorable season can it be dried sufficiently to safely pack in a mass under shelter, and the difficulty is in finding room for so much.

After all the available space under cover has been filled, often a large amount has to be left in shock, or otherwise disposed of out of doors, until wanted for use. In this way much labor is involved, as it is sometimes necessary to handle over two or three times, and there is, of necessity, more or less of loss from moving, and the effects of the weather.

These considerations, in our own case, led to the building of a silo, and more especially as winter dairying is now practiced, and more succulent food is wanted. Last year a thoroughly constructed silo was erected outside the barn,—there not being room inside to spare for the purpose—conveniently connected with the stable.

Five feet were in the ground, and the rest a substantial timber building, above, and large enough for a twenty-cow dairy.

It required a twenty-four foot carrier to elevate the ensilage to the door in the gable end of the building, but this worked all right.

We found it less work to put the crop in the silo than curing in the old way; and then as the field was clear, it could be plowed as soon as desirable.

The neighbors said it would take two years to raise corn enough to fill the silo, but it was filled, allowed to settle and filled again clear to the roof. It is astonishing how much corn can be put in so small a space. We estimated it cost 30 cents a ton to put in the silo, and $1 00 a ton for growing and siloing.

The ensilage has kept remarkably well, but with the experience gained should be able to do a little better in some respects another time.

Commenced to feed cows giving milk in November and expect to have enough to last until they go to pasture.

We find it much more convenient and easy feeding the ensilage, than the cured corn, as formerly practiced. Aside from the loss on top there is practically no waste, while with the cured corn there would often be considerable. I understand that the past winter it has been difficult getting stock to eat the cured fodder even fairly clean. Perhaps this was owing to the season which resulted in making the stalks dry and hard.

Formerly, the cured corn would last not much over half the winter; as ensilage, each cow gets twenty-five pounds a day, given at too feeds, till grass grows. In addition, they have morning and night, a feed of oat hay or mixture of clover and timothy.

At noon comes the grain feed, composed of bran, gluten and cotton seed, in proportion of 200, 125 and 100 pounds, respectively. Each cow gets five pounds of this mixture. Water twice a day. Water warmed in the morning.

The cows—except one that has since gone where there are no silos—are very fond of the ensilage. But in addition to its value as a feed, I think it helps to give the cows a better appetite for the hay, and with the care received, are sleek-coated, hearty and healthy.

The feed and care have resulted in a good yield of milk and butter. Never had cows do better on the best summer pasture. That the milk is of good quality may be inferred from the fact that it requires only seventeen and one-half pounds for one pound of butter. The butter has much of the aroma of that made on grass, and is well liked by consumers.

From this brief experience we are well satisfied with the silo and its results and consider it a great help in the dairy, especially where the cows are milked through the winter. E. R. TOWLE.

Franklin Co., Vt.

A Believer in the Escutcheon Theory for Judging Cattle.

ED. HOARD'S DAIRYMAN:—In renewing my subscription, after reading so much about milk and beef form and general purpose cows in your paper, I will give a little of my experience, as I am a breeder of Holsteins and breeding for the milk form.

My experience teaches me that it costs more to feed a cow that is bred for milk and beef than one bred more for milk. I have a heifer two years and ten months old that dropped her second calf ten days ago. She is of the milk form and gave last night and this morning (March 14th) forty-three pounds of milk. Her feed is, for the entire day, five pounds bran, four pounds gluten feed, fifteen pounds hay, and three pounds corn stover. I bought hay for $3 per ton delivered, so you see it don't cost much to feed her.

According to the Guenon system, this heifer gives very rich milk. Her mother was an imported cow and gave the richest milk of any cow I ever owned.

There are a great many signs by which to select a good cow. I place most reliance on the Guenon or escutcheon theory; you on the pelvic arch and incurving thighs. I can see that these are good indications, for my cows that have the highest pelvic arch are the best cows; but the beauty of the Guenon system is that you can pick out a calf when it is three months old and tell what kind of a cow it will make, and that is what farmers want to know.

I never raise a calf that does not have a good escutcheon, whereas the editor's advice is to get a Babcock test and scales and weed out the poor cows. It costs a good deal to raise a cow up to four or five years old to find whether she is worth keeping, and what will you do with her if you find you have a poor one? No one wants her.

I have studied the escutcheon theory for twenty-five years or more, and I know it to be correct. I have been judge at fairs a great many times, and I can tell more by looking over a cow in fifteen minutes than any man can by milking or testing her in one year, for cows will never do just the same two years alike. There are poor cows in all breeds and good ones. J. J.

South Hamilton, N. Y.

"Keeping The Cans Clean."

Something should be added to the editorial in last week's DAIRYMAN on this subject in regard to the importance of selecting milk cans that have no crevices inside in which milk can lodge and sour and smell. In buying a can, put your hand down between the breast and the body sheet, on the inside. If you can feel a square corner or crevice there, or if there are rivets going through the breast hoop, or if the can is soldered in bunches or not soldered at all, it will trouble you sorely to keep it clean. Any roughness on the inside of the can should be avoided. If the tin coating on the can is thin, or even a little imperfect, the metal underneath will oxidize, the milk will taste badly, and the can will soon rust out and go to pieces. There is a sure way of telling a good from a bad milk can. Turn the can upside down. If the makers are afraid of its quality, their name will not be on it, but if it is stamped with the Milk Can Trademark, no matter what its weight or pattern, you can bet it is the best Can you can get—for the money. Those who are interested in good cans should write to the BUHL STAMPING CO., Detroit, Mich., for their book entitled "A Study In Milk Cans," which is mailed without charge.

Holstein-Friesian Cattle.
Stock of both sexes for sale, from such families as Parthenea, Scolton, Pietertje and Netherland.
L. F. JUDD & CO., Bloomington, Wis.

Holstein-Friesians
MECHTHILDE BULLS FOR SALE.
Address M. W. BARDEN, Portage, Wis.

A Trio of Show Bulls
of the richest and most famous breeding in the world are the yearling bull Valencia Sir Mechthilde 25050, H. F. H. B., average butter record of dam and sire's dam, 31 lbs. 12 oz. in 7 days; average milk record, each, 100 lbs. in 1 day. De Kol Alban Astrea (25150), average butter record of dam and sire's dam, each, 32 lbs. 15 oz. Sir Tirania of Valley Mead (25146), grandson of both Tirania and Natsey. No three better bred or better individual young bulls can be found in America today. High class breeders can not afford to let this opportunity go by. Prices low for quality. Inspection invited. VALLEY MEAD FARM,
KARLEN & CO., Monticello, Wis.

GUERNSEYS AND POLAND-CHINAS.
Bred from the most noted prize-winners. Calves and Pigs at bargain prices. CLAYTON C. TAYLOR, Lawton Station, Erie Co., N. Y.

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. F. W. TRATT, Whitewater, Wis.

GUERNSEY Cattle—SHETLAND PONIES.—Old Homestead Herd was Champion at O., Ill. and Ind. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs. No better collection in America.
Breeding Stock for Sale. Inspection invited.
L. V. AXTELL, Perry, Lake Co., O.

Riverside Guernseys.
CHAMPION HERD
AT NEW YORK STATE FAIR,
1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by COMUS, sire of most of the winners, for sale. Thoroughbred Poultry—the best egg-producing and general purpose varieties—Leghorns Wyandottes, Buff Ply. Rocks, Houdans. Send for circular. Stock for sale. J. FORSYTH,
Riverside Farm, Owego, Tioga Co., N. Y.

"Florham" Guernseys.
First Prize Herd wherever shown, viz: New York State Fair, 1895 and 1897; Bay State Fair, 1895; Inter-State Fair, Trenton, N. J., 1895 and 1897; Madison Square Garden, 1895; New Jersey State Fair, 1897. J. L. HOPE,
Farm Supt., Madison, N. J.

GUERNSEYS.
225 Pure Bred Guernseys,
Of the best American and Island breeding. Butter average, whole herd, 318 lbs. per head. No catalogue. Come and make your own selection
ELLERSLIE STOCK FARM,
Rhinecliff, N. Y.

MILLWOOD FARM
Guernseys!
Guernseys of All Ages and Sexes For Sale.
Bred from Tested Dams. All animals have been tested with tuberculin and certificate of same is provided with each animal.
N. I. BOWDITCH, Framingham, Mass

AYRSHIRES Finely Bred and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited.
FRED TSCHUDY & SON, Monroe, Wis.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

HOLSTEIN-FRIESIAN CATTLE
Owned by JONES & RANDALL, Hustisford, Wis. 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

OAK GROVE HERD H-F. Cattle.
Cows, Heifers and Bull Calves For Sale.
C. H. Stevens, Jefferson, Wis.

SHADY NOOK HERD HOLSTEIN-FRIESIANS and CHESTER WHITE SWINE. W. R. GATES, Ripley, Jefferson Co., Wis.

McGEOCH FARM Holstein-Friesians.
Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to J. A. THORNTON, Mgr., Simonsville, Vt.

130 Holsteins. First prize herd at Trans Mississippi Exposition, at Omaha. 1st and 2nd on aged cows and 1st on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want, HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

Some Nuisances of the City Milk Supply.

Continued.

ED. HOARD'S DAIRYMAN:—I wished especially to call attention to

THE CITY DAIRY NUISANCES.

The honest and intelligent city milk dealer to a great extent has the control of the milk he handles. Even if he has a large business and draws his milk from a large number of dairies, most of which are located along the railroad lines, and maybe as far as a hundred or more miles away from the city, still he can to a great extent compel his patrons to furnish him only good, clean and pure milk and cream.

The only trouble is, that if he is too exacting the producer will seek another less careful buyer (of which we have only too many) and if a dealer insists upon pure milk, he will have to pay an extra price. But I can assure the average milkman, that while probably such an effort would reduce his profits temporarily, it will pay in the end.

In the city-milk-supply, certainly, the old maxim holds good: "Always room at the top." And the dealer who has pluck, intelligence and ambition enough to stick to it long enough is obliged to be a winner.

Let us examine some of the most common and mischievous nuisances which could easily be avoided and are only caused by the gross ignorance, carelessness and selfishness of the retail dealer, and just as much by the insufficient inspection and the inspector's lack of understanding anything, as to the nature of milk and the way in which it should be treated and handled in order to reach the consumer in as perfect and pure a condition as possible.

I am convinced that as long as men are employed as inspectors of dairies and milk who are ignorant in the dairy business, we shall never make much headway.

One of the first and main nuisances is

THE MILK SHIPPING CANS

and their condition. Anyone who will take the trouble to examine a lot of empty return cans, standing on some city depot platform, can soon convince himself on this score. First, lots of cans are used that even while new were unfit for transportation of milk, especially by rail.

It is strange, indeed, that for instance, any one selling or buying milk for city sale (and for that matter for manufacture of butter and cheese as well) would ever use any kind of can, where the cover will admit dust or impurities of any kind.

Yet, common sense ought to convince anyone that a can cover, which simply goes into the neck of the can, without any rim protecting the edge, must always leave access for impurities from the outside, more or less. No other cover should ever be permitted by the Health Boards than such where the rim of the cover perfectly protects the edge of the can.

A cover of any kind may accidentally, during transportation, receive a push, and be somewhat loosened, and then the chance for dirt to get into the can is still greater. On railroads, we even run the risk that something else is placed on top of a can, and goodness knows what might get into it. Never have a little hole in the cover, as some make "for ventilation".

If the milk or cream has been aerated and cooled as it should be before shipping, we need no ventilation, but want our cans as nearly hermetically closed as possible; that little hole, while no larger than a pin's head, is only there to let dirt in.

RUSTY OR BRUISED CANS

should be absolutely prohibited. Rust causes a tallowy taste, and bruises (which always mean rust also) furnish excellent living departments for bacteria of the most undesirable kinds.

To start with, have only cans made of the best material and by best workmanship. The can costing you a double price will prove the cheapest in the end, and it will be a long time before they get bruised or rusty even by railroad handling.

As long as they are properly cleaned and cared for at both ends of the trip, which they generally are not, you will find that even the railroad employees will handle a well constructed, clean and respectable looking can in a much more respectable way than an old rusty, bruised, dirty thing. There will be about as much difference in the way of treating cans, as in the way a conductor treats a gentleman or a tramp.

CANS WITH DIRTY BOTTOMS,

and otherwise, even of clean appearance, are a common nuisance, and it is a worse one than you think for. I have handled cans, where a collection of old manure, etc., was to be found under the bottom, which made me suspect that the bottom never had been cleaned since it was taken in use. I fully believe some never have.

The only way in which they are cleaned is occasionally by accident being placed in some pool in the road or outside the barn, and some old dirt gets away to make room for some new. This is no fancy picture.

The trouble caused from such dirty bottoms, both at the place of production and city dairy, is obvious! At either place the full cans are often placed in springs or ice water tanks, and especially in the city dairies it costs too much ice to renew the ice water daily.

Think now of this can, bottom collections over and over again, being placed in these tanks, and leaving a little there every time! It seems to me simply ridiculous that there is no law against dirty cans, as undoubtedly many disease germs are transferred in that manner.

SHIPPERS' CANS ARE FREQUENTLY RETURNED UNWASHED.

Sometimes they may have been rinsed out with cold water, but just as often not even that. Take the trouble to scrape with your finger nail along some inside seam of a return-can, as found on a city platform, and you will soon be convinced. Now let that little old milk stay there for hours, even for days sometimes, and in warm weather, and it will be a herculean task to have those cans thoroughly cleaned after they come back to the farm dairy, where they probably will be filled with milk again as soon as possible.

How can we expect milk, even the purest and cleanest, to keep sweet and fresh flavored when thus maltreated? Let us have a law that:

NO CAN ALLOWED RETURNED BY RAILROAD UNLESS ABSOLUTELY CLEAN INSIDE AND OUT.

This would surely be a very simple law to pass, and one easily controlled and of just as much importance to the producer as to the consumer. Can't we get such a law?

But while such cleaning would mean an immense improvement, still to be really efficient:

ALL CANS SHOULD BE STERILIZED OR STEAMED AFTER CLEANING.

This will be the only sure protection against transmittance of injurious germs. Of course an inspector cannot see if the can has been sterilized or not, but a law could be passed that:

No farm or city dairy should be permitted to sell milk in a city which was not supplied with proper arrangements for the steaming or boiling of all milk vessels used.

The farmer or dairyman once supplied with proper appliances, would not be foolish enough not to use them, as he very soon would discover the great advantage, to himself, of steam for sterilizing purposes.

As it is now, too much cleaning (so called) is done with luke warm or cold water, and too much final rinsing with cold and impure water, instead of hot water or, still better, steam.

Always finish all cleanings with hot water or steam, and you will also find it one of the best protections against rusty spots, which are the ruin of the cans and milk vessels generally. Let us have a

CITY STERILIZING LAW.

It would prove an immense help for the pure milk supply. In hot as well as in very cold weather, milk and cream cans should be protected by "jackets". We have received cream here during the entire year, which is fully from 6 to 9 hours in transfer by railroad and express, and it has always reached us in perfect condition for pasteurization, even in the hottest weather. The highest temperature, upon arrival, having been 56° F., but the normal temperature below 50° F.

If these cans holding 5 gallons had not been jacketed, the cream could never have endured such exposure, arriving here by 1 or

ZERO CREAMERY CO., PERU, IND.

Water alone will do the work. Money saved.

The Most Complete Creamery and Refrigerator on the Market

3 p. m., in the hottest weather. This winter, though always cooled below 50° before shipping, it never arrived badly frozen, and we had 15 below zero. But this leads us to the great importance of having

MILK AND CREAM THOROUGHLY COOLED AND AERATED BEFORE SHIPPING.

Without that, of course, the jacket would often prove worse than useless. The fact is that all milk for city sales should be cooled to 40° before leaving the producer; and as to straining and aerating, I hold that

ALL CITY MILK SHOULD BE RUN THROUGH A SEPARATOR

and cream and milk run back together again. As it leaves the separator, it should pass over some good and efficient cooler; especially see to having one easily kept clean. But after the milk or cream has passed over the cooler, the cans should at once be placed in ice water and the contents frequently stirred, as by so doing we reduce the temperature still more, and keep it as low as possible, until the time for shipping.

I have found that I can do better with milk and cream from the evening before, kept in ice water all night and shipped at 40° with jacket, than I can with morning's milk cooled only to 50° and shipped at once, thus being 12 hours younger than the other. Many do not believe this, but have a bacteriological test made, and you will find I am correct.

I must leave some other points for next time, as well as some hints about pasteurization of milk as well as cream.

Washington, D. C. J. MOLDENHAWER.

Seasonable Notes from Michigan.

Cost of Silage.—Oleo in Michigan.—Grading Dairy Butter.—Feeding Fat into Milk.

ED. HOARD'S DAIRYMAN:—March is always a trying month when stock of all kinds begin to feel the effects of the long confinement and dry food, usually their only resource from fall till spring.

Lucky indeed the animals which have succulent ensilage, well preserved as a daily ration during this period.

Speaking of ensilage reminds me of what Mr. A. M. Welch, of Ionia, one of the most intelligent and prosperous dairymen in the state, said at the Round-up Farmers' Institute, held at Pontiac last month.

He is most enthusiastic over the silo, and places total cost of growing and harvesting his ensilage at 40 cents a ton. Surely this is furnishing an ideal food at a surprisingly low cost.

Michigan is in a muddle over an oleomargarine bill, now before the legislative body of the state. House and senate have each a bill covering the same ground, but introduced under two different names and neither will give precedence to the other.

Meanwhile the oleo men are jubilant and are pushing their work in every possible way to defeat the action in unison of the two bodies. It is to be hoped that something will be accomplished, which will be effectual, since last year's law proved ineffective by reason of some technical defect in its wording. It is getting so there is no telling whether a law is a law or not now-a-days, when it is so easy to detect flaws, which proves them inoperative.

But one thing is certain, there ought to be something done which will protect the farmer from injustice, and not allow hog butter to be sold for the pure product of the dairy.

Let each be sold strictly on its own merits and for what it really is. We ask nothing more than this, which certainly is a reasonable and just demand.

I was talking with a grocer who handles considerable butter, not long ago, in regard to the practicability of grading it, buying and selling it entirely upon its merits.

In his own practice he refused to buy poor butter at all, but pays the same price for all that passes inspection. He thinks if dealers would unite in refusing to buy poor butter at any price, it would result in great benefit to all concerned, and in the end force makers to better the quality of their product.

As long as a single grocer in any town will take whatever is offered and pay the same price that he does to those who make good butter, the others can do little to improve present conditions. It requires considerable courage to refuse to buy from regular customers the butter they offer, and loss of trade would surely result.

If every dealer would be firm in doing this, however, one can see that it would shut out all that is undesirable, and those who make it, would be forced to improve their methods.

It is true that some are surrounded by great inconvenience in attempting to make good butter, and a visit to some farms would show that conditions under which the buttermaker labors are distressingly adverse to best results.

Yet I believe it lies within the power of nearly every woman to so arrange her dairy equipment, as to turn out a fairly good article, if she so wills it.

Tin pans and dash churn have turned out some of the very best butter that has ever been made. An earnest desire to succeed is pretty sure of accomplishing its object in this, as in everything else.

As the season advances, there are pretty sure to be some foolish ones who are anxious to get their animals out to pasture. The result of turning them out too soon will be seen in a few weeks.

The grass cannot get a good start, but is cropped close to the earth, whereas a few days' delay in turning out would have given it a growth which would have enabled it to hold its own against the onslaughts of the stock, hungry for a stomachful of the toothsome herbage.

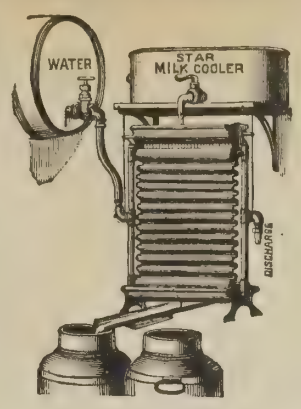
Young stock, calves in particular, need extra care when turned out to grass for the first time. They will miss their mess of milk and should have a generous grain ration every day. It cannot be too strongly urged that this be done. Do not allow them to fall away, for such loss is a serious detriment to future development.

Again and again does that question of feeding fat into milk arise for discussion. Argument availeth not to convince the average farmer that it is impossible to feed fat into milk.

They cannot bring facts and figures to show this, but have a convincing belief which is as unchangeable as the laws of the Medes and Persians. Ought not the result of experiments under such men as Clinton D. Smith, director of Michigan State Experiment Station, to be accepted without demur?

This seems to be one of those abstruse questions which are difficult to explain to the satisfaction of those who have relied upon tradition and their own opinion for solution. Like the one relating to the elaboration of milk in the cow's udder, it has not been accepted without objection by those who have long held contrary opinions.

The best way is to say that those who have made it a study are better prepared than any one else to know the truth in regard to the matter, even though it may entirely disagree with preconceived ideas on the part of the individual. There are plenty of accepted beliefs and opinions which are not truths.



In this case of feeding fat into milk there are a large number of men who refuse to accept proof regarding the subject, simply because it disagrees with the opinion they have always held.

Genesee Co. W. C. ROCKWOOD.

Knowing How to do Things.

Success never follows ignorance or slip shod methods. There is a creamery up at Beloit with branches in several different counties that is making money hand over fist. Half a dozen men went down in the effort to maintain a creamery at that point; lost money right and left. But one day a couple of young Danes, the Jensen Bros., came along and took up the work where others had made such dismal failures. They succeeded. There was no "luck" in it at all. They simply understood their business. They knew how to "do things."—*Topeka Kansas Capital.*

There is the same difference in success in dairy farm management that there is in creameries. All over the land will be found men taking milk to the same creamery, one losing money, or just barely starving along, the other doing business at a profit. It always pays the biggest kind of returns to learn how to "do things," and farther, to keep learning.

Star Milk Aerator AND COOLER.

If you have milk worth cooling at all, it is certainly worth while to cool it thoroughly. An efficient Milk Cooler will cool to within two degrees of temperature of water used; the Star does this and also AERATES.

If you would like to know the reason why, send for 1899 Catalogue of Sanitary Dairy Apparatus.

To be had for the asking.

STAR MILK COOLER CO., Haddonfield, N. J

Victor

ANY OLD STRIP OF TIN . .

With two nails will fasten the cover. Butter makers who care for the appearance of the package use the VICTOR. Strong and smooth. No tacks or sharp corners to injure the hands. C. E. Smith & Co., Westboro, Mass.

Castor Oil for Calf Scours.

ED. HOARD'S DAIRYMAN:—In regard to treatment of calf scours, I give four tablespoonfuls of castor oil at a dose. One dose is generally sufficient, but if not, I follow it up with another in about twenty-four hours, but seldom have had to give more than one dose. Of course a person would have to use his own judgment in regard to that. In fact, I have never paid as much attention to the time between the doses as I would if I had thought of writing it up.

It seems that a large dose of oil physics them out thoroughly and then checks the discharge from the bowels.

One man told me that he gave his calves (when they had been troubled with scours) a dose of castor oil soon after they were dropped, and had been very successful. I have never lost a calf that I have given oil, and have had them so bad they could not stand up. E. E. WHEELOCK.

Whiteside Co., Ill.

SICK WOMEN

are invited to consult Dr. R. V. Pierce, chief consulting physician to the Invalids' Hotel and Surgical Institute, Buffalo, N. Y., by letter, without fee or charge of any kind. Dr. Pierce is a specialist in the diseases of women. He has treated over half-a-million women for diseases of the womanly organs and ninety-eight out of every hundred women he has treated have been absolutely and perfectly cured. Every letter received by Dr. Pierce, is treated as a purely personal and private communication and its contents guarded as a sacred confidence. All answers to these letters are sent in sealed envelopes bearing upon them no printing or advertising whatever.

Write to *the doctor*. It is no use for sick women to write to a man unless he is a doctor. It is no use to "write to a woman" unless the woman is a doctor. Write to a woman about cookery or any branch of housekeeping, because she is a woman and knows. But it is of no use to write to a woman about disease unless she has a doctor's training and diploma. **A woman who isn't a doctor is just as dangerous as a man who isn't a doctor, when she undertakes to treat disease.**

There is no qualified woman physician so far as is known connected with any proprietary medicine put up for women. Even the "bearded woman," the *man* who advertises "write to a woman" is not a qualified physician and stands too much in fear of the law to claim that he is.

There is no other physician, male or female, who, like Dr. Pierce has a record of over thirty years, as chief consulting physician of a well known institution, making a specialty of the private treatment of women's diseases.

Write to *the* doctor—Dr. R. V. Pierce, Buffalo, N. Y.

Women realize Dr. Pierce's ability when they read his great work the Common Sense Medical Adviser, 1008-pages; sent free on receipt of stamps to defray expense of mailing *only*. Send 21 one-cent stamps for paper-bound edition, or 31 stamps for cloth. Address Dr. R. V. Pierce, Buffalo, N. Y.

A Good Text for a Dairy Sermon.

Hoard's Epistle to the Dairymen No. 1571 Page 207.—*Multum in Parvo.*

ED. HOARD'S DAIRYMAN:—"Cold water, cold barns and cold air have to be heated with butter fat, if the cow is to keep herself warm."

My brethren, costly heating isn't it?. Yet how true.

In the first place, to illustrate the force of the foregoing true passage of dairy gospel, let me say I have two neighbors, good friends—both readers of the DAIRYMAN,—men I like to associate with; both men are good farmers, both keep good cows. I'll call them No. 1 and No. 2. They live only half a mile apart.

No. 2 said to me the other day: There are some things I cannot understand. I raised last season, double the feed that No. 1 did, and I farm double the land he does, but I am about fed out of corn, hay and fodder, and he has a large crib of corn untouched; a large stack of unfed stalks, and plenty of oats and hay.

We milk about the same number of cows, and No. 1 has a better yield of cream than I have. My barn is quite warm except when south wind blows. I turn them out only to drink, and have a tank heater, and put them in when stables are cleaned. His cows look well, and yet it seems to me, I feed twice the amount he does.

So to help him out I said, "I think I can English it." In the first place, No. 1's cows have had continuous stabling for seven winters, from November 1st to May 1st, each year. Most of his cows never breathed cold air. Every visitor who goes there, Briggs & Stiles included, say, O how hot it is here; the air must be bad; why, it makes me sweat.

Now this barn is continually kept nearer blood heat, than any I know of; hardly an ounce of feed is used to keep up animal heat.

The milk in the cow—or after it is drawn, is about the same temperature; the water tank in the stable is the same—no animal heat used to warm it after being drank. All his feed is used to sustain life and produce cream.

Now secondly, I said, your barn is not so warm as his, and though your tank heater warms the water, your cows are all turned out to drink and remain out one to two hours, or longer,—barn is opened, stables cleaned. Temperature goes down from 30° to 60°, then when the cows are well cooled off, they are put back. What warms the barn up again? Why, it must be the excess of feed you use, over and above what he uses.

My friend said that must be the reason. According to the text it is heated with butter fat, and it takes feed to make that.

Now, thirdly, is this a healthy way to keep cows, and is it profitable? Well let us reason together and see. Seven years ago No. 1's herd produced less than 300 pounds each per year, quite a little less, but since continuous stabling in winter, they have gradually increased to over 400 pounds per cow, and two individual cows produced over 500 pounds each last year. All are grade cows, look sleek and fine. He has had no abortion in herd, calves and yearlings kick up their heels, and play in their stalls, and I believe a visit to that barn would make that noble man, Geo. T. Angell, of Boston, smile and feel happy, and say, "Surely one man in Wisconsin practices what I preach, to wit: kindness to dumb animals."

Now as to profit: If No. 2 makes any money by keeping good cows, and feeding the crops of one hundred acres to them, do you think No. 1 makes any profit feeding the crops of fifty acres to the same number of cows for the same yield of cream? Surely, yes.

Is there not some food for thought in the foregoing, and can dairymen not profit by it, and govern themselves and their cows accordingly? If the Creator made blood heat the temperature it is, it seems to me the nearer we can keep the temperature of the barn there, the better, though I heard a student at Madison last winter say, that he understood that the Station cows produced better when the barn was kept at 40° to 50°, than when higher.

A visit to Mr. Cate's barn, at Amherst, last winter convinced me that a room with a good hot stove in it, opening into the cow stable, on a cold day, made the inmates look happy, comfortable and contented.

I was going to say fourthly, but Goodrich said fourthly blew out of the window some time ago, so I bring my remarks to a close.

La Crosse Co., Wis. A. J. PHILIPS.

Bro. Philips is quite right in the main, but we cannot agree with his conclusion, that the temperature in the stable should be kept up to "blood heat", which in the case of cows is 100°, or a little more.

The bodies, whether of men or cows, contain wonderful and mysterious furnaces, and if there was no provision for the escape and dissemination of the resulting heat, it would accumulate to an unendurable and dangerous degree. On the other hand, as the cases cited by Bro. Philips amply prove, and as the experience of every individual attests, when subjected to temperatures approximating the freezing point, these internal furnaces must consume more fuel (food) and then are often unable to maintain bodily comfort. Here as elsewhere, *in medio tutissimus ibis.*

Varieties of Corn for the Silo.

ED. HOARD'S DAIRYMAN:—Now is the time that the silo men are considering what are the best varieties of corn to plant for this purpose.

I would like to give through the DAIRYMAN the results of our experience with this part of the silo question for the past fourteen years, and also the opinion of some of the best dairymen of this section.

It was my privilege the past winter to visit some thirty silos in this vicinity and note the quality of the silage. In a majority of the cases where the dairymen had been using the silo for a number of years they were filling with some of the dent varieties, either yellow or white.

The best silage was from the dent varieties of corn, when they were cut for the silo when the the ears were well glazed, or just beginning to dent, and the lower leaves were dying. When put up greener the silage contained a larger per cent of acid, and if allowed to become too mature it was found to be moldy in spots and in some cases in layers, extending over the entire surface of the ensilage, even below ten feet of good feed.

The southern varieties of corn make quite an acid silage. The chief cause of this is that they do not sufficiently mature. In our section they rarely become anywhere near mature before frost.

It is best to have a small part, say, ten per cent of the crop, of some other southern kinds, for they possess certain qualities which are not found in the other varieties.

Their ability to withstand a long drouth in summer is surprising. They will produce a larger amount of feed per acre. That they will produce a greater amount of feed value per acre, in an average season, is questionable.

My plan is to have a small amount of some of the early varieties, and, as just stated, a certain per cent of the late, with the main bulk of the crop of some of the dent varieties.

By this plan, not only the time of filling the silo can be extended, but the planting season as well. The flint varieties can be planted quite late and in an ordinary season will produce a good crop. Two years ago I planted some yellow flint on some low land, which did not become dry enough to work until July, and yet we got a good crop.

The southern variety should be planted soon after the dent. When several varieties are grown the work of filling the silo can be commenced sooner than where we depend entirely upon one kind.

One advantage of this is that it will not be necessary to hire as much extra help at filling time, for if the first variety becomes too mature, we can commence on the next, and so on. As the number of silos increase this is a matter which must be considered, for help will then be even scarcer at that time than it is now.

The southern varieties stay green almost any length of time, and thus we have a good heavy kind to fill in on top of the rest to help pack and preserve it.

Where one variety is depended upon there is danger of getting the driest feed at the last, just where the heaviest is needed.

WILBER F. STILES.

Jefferson Co., Wis.

THE LARGE PROFITS OF THE NEW YORK MILK TRADE.

The Five States Milk Producers Association have prepared the following array of figures to show the enormous profits reaped by the New York dealers out of the milk trade. These figures are also instructive for all dairymen, on general principles. The milk is figured to be sold at five cents a quart, when, as they claim, that most of it is sold for six, eight and ten cents a quart:

The farmers are only paid from one, and one-eighth, to two and one-third cents a quart, and in this estimate they are allowed two and one half cents.

The 24,000 cans of milk that are each day sold in the metropolis, at five cents a quart, would bring $17,520,000 in a year. A daily consumption of 600 cans of cream, at 25 cents a quart, amounts to $2,190,000, making a total of $19,710,000.

The annual expenses are figured as being: The cost of milk at two and one-half cents a quart, $8,760,000; freight, at 30 cents a can, $2,628,200; cream at 10 cents a quart, $1,095 000; freight on cream at 40 cents a can, $87,600; labor in 350 shipping stations, figured on a basis of $50 a month for each employé, $210,000; icing stations, at $200 each, $70,000; 1,000 delivery wagons labor, at $3 a day, each $1,095,000; 1,400 horses at $1 a day each, $511,000; salaries, clerk hire, etc., $202,000; making a total of $14,658,800.

This would leave a net profit, according to this committee, of $5,051,200.

Food Tests of Holstein Friesian Cows.

ED. HOARD'S DAIRYMAN:—Among those of the present official year, not previously given to the public, are the following:

DeKol Manor Beets; age 2 years, 1 month, 15 days; food consumed, pasturage, pea meal 11.83 lbs., ground oats 11.83 lbs., ground barley 11.83 lbs., ground buckwheat 11.83 lbs.; product, milk 307 lbs., butter-fat 9.695 lbs; representative of Cornell University Station, H. C. McLallen.

Mutual Friend 2nd; age 6 years, 6 months, 26 days; food consumed, ensilage 434 lbs, hay 36 lbs., wheat bran 45 lbs., cotton seed meal 3½ lbs., ground oats 5 lbs., corn meal 15 lbs.; product, milk 427.4 lbs., butter-fat 14 724 lbs.; representative of Cornell University Station, A. R. Ward.

DeKol Lady; age 1 year, 11 months, 2 days; food consumed, pasturage, pea meal 11.83 lbs., ground oats 11.83 lbs., ground barley 11.83 lbs., ground buckwheat 11.83 lbs, product, milk, 312.4 lbs., butter-fat 9 384 lbs; representative of Cornell University Station, H. C. McLallen.

Aggie Paul, age 2 years, 2 months, 2 days; food consumed, ensilage 203 lbs., hay 7 lbs,. wheat bran 28 lbs., oil meal 16 lbs., corn meal 30 lbs., ground oats 14 lbs; product, milk, 280.3 lbs., butter-fat 11.303 lbs.; representative of Michigan Station, Porter H. Davis.

Clothilde Artis Topsy; age 4 years, 1 month, 10 days; food consumed, pasturage, malt sprouts 21 lbs., gluten meal 7 lbs.; product, milk 412.8 lbs., butter-fat 13.724 lbs.; representative of Cornell University Station, Leroy Anderson.

Paula Dorinda; age 2 years, 10 months; food consumed, ensilage 363 lbs, hay 13 lbs., wheat bran 80 lbs., oil meal 31¼ lbs.; product, milk 343.2 lbs., butter-fat 11.101 lbs.; representative of Michigan Station, Porter H. Davis.

ILLUSTRATION.

The above is cut of the Havana all steel Handy Wagon. Concerning this wagon they write us as follows:

"Our all steel Handy Wagons have grooved tire wheels that are made so as to protect the ends of the spokes. We can assure our customers that one set of wheels made with the grooved tires will outlast three sets made with the ordinary flat tires. We know this to be a fact. We are also making grooved tire truck wheels for farm wagons. This is an important feature. An investigation before buying is earnestly solicited." HAVANA METAL WHEEL CO.

Havana, Ill.

ILLUSTRATION.

The day of delivery of your milk product by surry, or some improvised vehicle is by. The National Wagon Co., Chillicothe, Ohio, have kept pace with the times, and to-day their National Low Down Cut-under stands without a superior. The management of the company two years ago decided to confine their entire energy and the capacity of their immense shops to the building of a Dairy Wagon, combining every possible point of convenience and durability.

A glance only at the showing of wagon will satisfy you that it is low hanging, and short turning, built especially either for the carrying of bottled goods, or by can system. Two sizes of the wagon are built to meet the demands for the lighter or heavier wagon.

The company have an unprecedented business this year, having shipped into every state in the Union, Canada and Cuba, since the first of January.

One of the company's artists has just completed a very fine engraving which is titled "The New Dairy Wagon." It is a picture full of interest to every dairyman, and would well adorn the walls of home or office. It can be had for the writing for it to the National Wagon Company, Chillicothe, who would be only too pleased to mail you one for the asking.

The Oat Question.

The great loss in the oat crop last year through lodging, and the consequent weakening, if not total loss, of the stand of clover, has made farmers study the oat question this spring as they never have before. Every bushel of early oats that can be had will be sown. Some are inquiring as to whether black oats will stand better than the white on corn land yielding from fifty to sixty bushels an acre.

We have discussed this question quite fully. We do not believe that there is any kind of oats ever grown that will stand up in a wet year on rich ground. There are only three things that we see, for farmers to do. One is to secure the earliest variety of oats that they can and sow them early. The second is to mow or pasture them off in case they threaten a too luxuriant growth. The pasturing should be done with sheep and unfortunately only a few men can do it successfully. To do a good job of pasturing requires three or four times as much stock per acre as it would ordinarily bear. A man with a large flock of sheep or with plenty of young cattle could manage it, and while this method is practical, it is so only for a few farmers. Most farmers will find it better to mow, but here again great care will have to be exercised. The mowing must be done before the oats are jointed, and then the mowing must be confined to simply clipping off the tops so as not to interfere with the head. We have known some successful jobs of mowing done last year in each of these forms, but it is not work for a boy or a man without mature judgment. If, notwithstanding all this, the oats lie down, then the only thing remaining is to mow them at once and make them into hay. This will secure a hay crop of the best kind for young cattle and dairy cows, and save the young clover.—*Wallace's Farmer.*

CONCERNING OUR ADVERTISERS.

PROFIT AND COMFORT.

Both profit and comfort are combined in the use of Kilfly on your milch cows. The comfort comes to both the herd and the milkers, while the increased yield of milk represents the profit. The cost of the liquid and the appliance for spraying it over the cows, is but nominal, and is soon paid for by the added profit in the increased "giving down" of milk—with the comfort thrown in. See the advertisement elsewhere in this issue.

EXPANSION.

Expansion is a word much in use It is a word which expresses the new political atmosphere. Breathing this new political atmosphere men argue and parties divide, but there is neither arguing or division about one kind of expansion which has been going along in agricultural circles for nearly seventy years. It is the greatest expansion for their benefit which the farmers have ever known. It is the expansion of the sales of the McCormick. Last season the McCormick Company built and sold 189,760 machines. This kind of expansion dwarfs every other achievement American history records in favor of the well being of the farmers. Buy McCormick machines and you get your money's worth.

BALL BEARINGS DID IT.

Bicycles were invented centuries ago, but it required the magic touch of the nineteenth century inventor to make the "wheel" a most useful vehicle, instead of a mere toy.

Ball bearings did it. It was a case where the improvement has proved greater than the original invention. The principle that reduces friction to a minimum in a bicycle is applicable to all machinery, and the cost is the only obstacle in the way of what will be known in history as the "Light Draft Era" in mechanics. Millions of dollars have been spent in this direction. The Deering Harvester Company, of Chicago, solved the problem, so far as grain binders and mowers are concerned, by equipping their machines with roller and ball bearings in 1891.

Other manufacturers in this line have since followed with several kinds of experimental roller bearings, but the Deering machines are still alone in the field with ball bearings of the bicycle pattern.

The Deering Company's annual catalogue for 1899 contains some very interesting historical matter on this subject, fully illustrated. The book also describes the largest factory in America and gives the latest news on the subject of harvesting machinery. Send for one; it's free.

THE aeration of milk is rapidly becoming one of the most important objects that the farmer has to deal with in the disposal of the product of his dairy. The reason for this is, that the managers of butter and cheese factories, and consumers of large quantities of milk in the cities, are daily learning, by experience and from acknowledged authorities, that milk that has been aerated, while warm from the cow, is freed of all foul odors from the animal, or taint from turnips, rag weed, or other vegetables on which the cow may have been fed. Aeration also adds from ten to thirty hours to the sweet-keeping qualities of the milk, and increases the quantity of cheese or butter that may be made from a given number of pounds of milk.

The aerator manufactured by W. H. Young, of Aurora, Ill., and advertised steadily in the DAIRYMAN, is a very simple device and thorough in its work. Circulars can be obtained by addressing as above.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

UNABLE TO STAND.

I have a cow that got down about three weeks ago. She is farrow and had been dry some weeks. I was feeding her just on roughness with the stock cattle; had cane hay, corn fodder, crab grass hay, etc, but no grain. Found her down in shed one morning, got her up; she seemed all right, and went out in pasture with the rest, laid down during the day and we can't get her up. I thought it caused by lack of grain feed. Began at once to feed oil meal, shorts, bran, some ground kafir corn, also oats and hay. She eats heartily and does not seem sick, but she can't be got up; she will get part way up and change position from one side to the other, but if we try to help her she won't help herself at all. My neighbors say I might as well kill her, as they have had such experience and never could save one. J. K. G.

Chanute, Kansas.

ANSWER.

No. I am sorry to say that at this late date of ailment I can't suggest anything likely to help the cow. Three weeks is a long time to defer asking advice which might have helped her at the beginning. After a cow has been down as you say, etc., there is but a slight chance, if any, of recovery. I don't believe the feeding, as you suggest, would have done good. Don't know the cause of the paralysis. There are many. I think some injury was the cause in your case. I would not recommend further doctoring. Don't believe anything you can do will pay you or help the cow.

LOSS OF MILK.

I have a splendid young cow. Last year gave a pailful of milk at a milking when she calved. Now she has not a drop of milk. Her teats are closed, appear soft and natural; up in her udder appear small lumps. Would you advise using milk tube? What kind, or shall I try to dry her up? What to use on the udder to take down swelling?.

Pleasant View. D. L. J.

ANSWER.

Immediately full dose of physic and repeat in 5 or 6 days. Then repeat in one week. Besides the physic, give 70 to 80 grains of iodide of potassa each morning as a small drench, in half a teacupful of cold water. The wind bloweth where it listeth, so do such diseases of the milk apparatus, etc. Let her alone until next calving. She will come O. K. then, more than likely. If you can milk her, do so thoroughly. See ads. in DAIRYMAN as to best milk tube. Rub camphorated spirits well into the swelling, six to two ounces of turpentine. Rub hard once a day for three or four days.

CALF NOT DRINKING.

We bought a new milk cow in March. Cow had been fresh about 10 days; calf would drink. We brought her home; she walked about 4½ or 5 miles in new snow. The calf drank good the first two feeds; since then has not drunk good; very slow and has been getting very poor. Will not drink over 2½ quarts. The cow is 7 or 8 years old; has lived in one place; perhaps she is homesick. Is the calf home-sick, or was it in the milk at the first feed? A. S.

Labarge, Mich.

ANSWER.

I don't think you need trouble about your calf. It will come round to its feed again, no doubt. Put ten drops of nux vomica in the milk for 3 to 6 days. Be carefull. Give good out door exercises in the sun, if not too hot. If the nux vomica is too bitter for the little fellow, give it one dram of fluid extract of golden seal, for 2 to 4 doses.

WHOLESALE USE OF POISONOUS DRUGS.

J. C. R., of Missouri, writes a long letter detailing the cases of two cows that he has been doctoring (?) very heroically.

He has given the first one, since the first of January, about 10 pounds of salts, 3 ounces of aconite, besides saltpeter and other things, and is still giving 20 drops aconite, four times a day, and notwithstanding all this, the cow is getting worse all the time.

Cow No. 2 calved April 9th, and although fed salts and aconite, failed to clean properly. About the ninth day udder became badly inflamed, and salts, saltpeter and aconite (20 drop doses 5 times daily for 3 days) were administered. At the time of writing (April 23d) the daily number of doses of aconite had been reduced to three.

To this letter Dr. Horn makes the following:

ANSWER.

Case No. 1 is beyond any help from me. How she lived, with aconite enough (if good) to kill half a dozen cows, is beyond my knowledge.

Case No. 2. Such wholesale administering of one of the most deadly vegetable poisons, is evidence of great ignorance of its properties and probable effect. After such exhibitions of dangerous medicines, I am quite unable to form even an appropriate estimate, as to the present condition of your cows.

CALF SCOURS.

A neighbor had nine yearling calves that died last winter. They had scours all winter. He opened some of them and discovered that the calf's gall was larger than its liver. Its liver was saturated with gall and the lining of the stomach had disappeared. Its digestive organs seem to be turning to gall. L C.

Montesano, Mich.

ANSWER.

Something in the food caused the liver disease; what this was I am not just prepared to say, as there are several forms of food likely to cause disease of the liver. The scours in your case shows this in the affection of the liver. The cure would have been the prevention.

REMOVING A CURB.

What will remove a curb from horses leg, brought on about one week ago working on farm? Horse is five years old. M. S.

ANSWER.

Perfect, absolute rest. After the inflammation is over, cut off the hair and apply the Gombault's Caustic balsam; quit for a while. When the blister is good, cover with hog's lard until scabs are off. Then repeat.

RUPTURE.

I have a nice cow due to drop calf May 10th, and seems to have broken down. I can't think of any other name as appropriate. About two weeks ago, her belly broke down, so that the bag is far up on side of stomach She eats well, and seems to be in perfect health. Is there any help for her?

N. Rupert, Vt. W. B. D.

ANSWER.

The symptoms point to a dead calf, or rupture. To get the proper diagnosis, a personal examination is needed by a competent veterinarian.

MANGE.

I have a pure Holstein calf, 10 weeks old, which about 3 weeks ago had a breaking out on and around her ears. I applied chloronaptholeum—it seemed to blister the part. The trouble has spread over her body, nearly. The hair comes off, leaving the skin dry and hard. She eats well.

Newburg, O. E. A. A.

ANSWER.

Mange. Cleanse with tar soap and hottish water. Then rub in pyroligneous acid, two ounces, oil of tar, one dram; fish oil, three ounces. To be thoroughly mixed and kept in a dark place out of the sun. Twice a day for a few days. Keep aloof from the herd, or they will be likely to become infected.

MANGE.

Our young cattle have a skin disease which looks something like bee stings only there is a yellow, waxy, crystal form in the center of each of these little lumps. They do not seem to be sore to touch. They generally begin on the animal's head and spread over the neck and belly, and on the legs, but not on the upper part of the body. They are not easily seen, but easily discovered by passing the hand over the animal, as they are very close together. J. M.

Oscoda, Mich.

ANSWER.

If not itch, scabies, or mange, I don't know what the disease is. Of course the three above skin diseases are all mange. Immediate full dose of physic; wash as above for mange, and prepare the same mixture exactly, but six times as much. Follow the same treatment exactly.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM. HORNE, Janesville, Wis.

NOT long since a dairy farmer, not a thousand miles from this city, was ridiculing an article he had read in HOARD'S DAIRYMAN, about the necessity of guarding against the dust that falls from unbrushed cows in the stable. His wife spoke up and said:

"Well, Tom, I agree with the DAIRYMAN. Every morning the milk you bring in looks as if you had peppered it."

Then Tom went out swearing that "women have no sense."

Cross Breeding of Jerseys and Holsteins

ED. HOARD'S DAIRYMAN:—Please state in the DAIRYMAN why you oppose crossing of Holsteins and Jerseys. Will not such a cross increase the milk of the Jersey and the butter fat of the Holstein?

Grant Co., Ky. W. H. DAUGHERTY.

The position of the DAIRYMAN on this question has been taken as the result of considerable observation along the line of such cross breeding with grade cattle, where registered sires, either Jersey or Holstein, were bred to grade cows of the opposite blood.

In theory, the cross ought to result as Mr. Daugherty suggests, but practice does not always justify theory. It appears to us that the prepotency of the Jersey and the Holstein are so strong and variant, especially with the latter, as to set up a conflict rather than such a union as is desired.

The result in the majority of cases that we have noticed has been what is called an "unfavorable nick."

There is shown a peculiar uncertainty in the character of the subsequent progeny for several generations. We take it that there is, in one sense, too much of the "dual-purpose," and that these purposes being widely apart in their tendencies do not knit well together in such a way as to create a constantly enlarging and harmonious current of dairy blood, purpose and character. As a rule in breeding, it is not wise to unite two strains too widely apart in tendency and in character. In such cases there is apt to result a lack of harmonious nicking as it is called.

Ascertaining the Real Value of Silage.

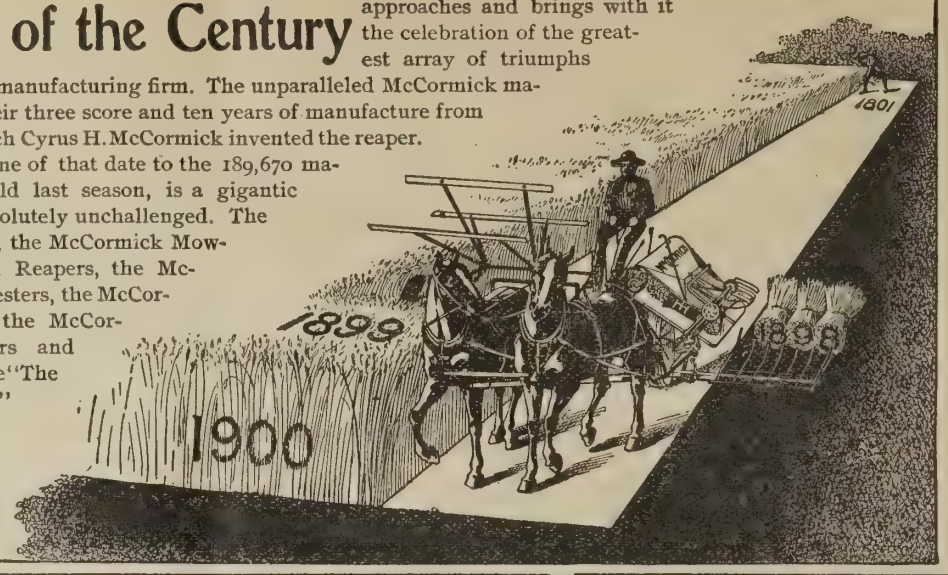
ED. HOARD'S DAIRYMAN:—I see by the label on my paper that my subscription has expired. Enclosed you will find $1 to renew the same.

Confirming what you have so often published, I myself can say a few words about my silo feed. I have been feeding silage for eight years and did not know the real value of it until now.

I fed the last of this year's supply the 28th of March. The third day thereafter, although the cows had the best of clover hay and the same amount of grain, the yield of milk for the twenty-two cows decreased 100 pounds. So I think I know the value of silage to me to be about $1 per day more than the best clover hay.

Spring very late here. Snow not all gone yet. A year ago today, April 10th, I was seeding. J. D. McA.

Mills Center.



Salting the Cows.

We have found from a sad but glorious experience, that cows need salt, not when you think they do, but when they think they do. Nothing could be more irregular than the way the average farmer sets up the salt to his cows; when he happens to think of it he scatters some salt along the ground, and the mad, feverish haste with which the cows go for it show that they have been hungry for it a long time; and when the farmer doesn't happen to think of it, the cows don't get salt. Other farmers mix salt with the cows feed, and that is a worse plan yet, for it is better to feed too little than to force too much. The best and only sensible plan is to place salt where the cows can get it where and when they want it.—Nebraska Dairyman.

The advice of our contemporary is all right for men who have no judgment or prefer not to use what judgment they may have. It is as good practice to mix salt with the feed for the cow as to mix it with the food prepared for men. Let the allowance be from three-fourths of an onnce to a full ounce, daily, for moderate feeding with a proportionate increase when the feed is ncreased.

The End of the Century approaches and brings with it the celebration of the greatest array of triumphs ever credited to one manufacturing firm. The unparalleled McCormick machines will reach their three score and ten years of manufacture from 1831, the year in which Cyrus H. McCormick invented the reaper. From the one machine of that date to the 189,670 machines built and sold last season, is a gigantic growth of output absolutely unchallenged. The McCormick Binders, the McCormick Mowers, the McCormick Reapers, the McCormick Corn Harvesters, the McCormick Hay Rakes, the McCormick Corn Huskers and Fodder Shredders are "The Best in The World."

McCormick Harvesting Machine Company, Chicago.

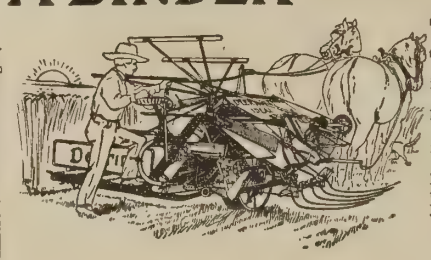
Milk Fever.

The New Jersey Experiment Station issued an excellent bulletin on this disease, and we give the following extracts from it. It is claimed that one form of the disease is caused by germs. This may account for the fact that, in some herds and barns, milk fever seems to be contagious like abortion.

The efficacy of the wet-pack or "sweating" system of treatment in this, as in all fevers, depends on the fact that the sweat glands remove the poisonous products that have accumulated in the blood. In fact, the paralysis produced by the poisons absorbed from the womb, probably, also extends to the kidneys, so that those organs cease to remove the ordinary poisonous excreta made in the system. Thus we have here really a double poisoning. It has also been suggested that there may be poisonous products manufactured by germs in the udder, which are absorbed.

The old theory of the cause of milk fever explained the disease as a sudden over-distension of the blood system, due to the accession to the general circulation, after calving, of the blood which flowed in the uterus before calving. This factor, probably, enters into the question, but there can be no doubt that bacterial poisoning is the principal cause of the disease.

TREATMENT AND PREVENTION.—Treatment should begin a week or two before the calf is expected, and should be practiced on every cow whose condition is such as to lead the owner to fear the occurrence of milk fever when she calves. The treatment is to continue for a week after calving. Begin giving short rations, feed sparingly of rich food, such as grains and clover, rather give apples and bran mash. Give salt to provoke thirst, and encourage the cow to drink, by warming the water if it is cold. Large doses of Epsom salts, a pound to the quart of water, may be given once or even twice a week, to provoke an unwonted activity of the bowels, and to counteract the tendency to constipation. If the udder is distended, it should be rubbed and milked regularly. The cow should be kept in a place which is dry, clean, airy and cool (in Summer) or warm (in Winter), and away from the other animals. Should the owner fear that his method has not succeeded in reducing the blood sufficiently, as may happen when the time is short, a veterinarian should be called to let out several quarts of blood from the jugular vein of the neck. Just before calving, the vagina should be washed out with a generous injection of two per cent creolin solution, which should be repeated daily after calving, for a few days. Immediately after the calving is completed, the veterinarian should inject creolin solution into the uterus, as in cases of abortion. Neither carbolic acid, nor corrosive sublimate nor iodoform can be recommended for disinfecting the genital passages, but these disinfectants and others may be used liberally upon the soiled bedding, barn floor, etc. If the cow is down, she should be propped up on the brisket to prevent the running of food into the lungs from the stomach.



Oh, what shall the har-vest be?... Oh, what shall the har-vest be?

NOTES ABOUT A BINDER

WITH SPECIAL REFERENCE TO THE DEERING IDEAL.

If it were lacking in any of those qualities which farm use has demonstrated to be the prime requisites of a grain harvester it would not be Ideal. In the **Deering Ideal** there is nothing lacking.

1. The Deering Ideal is strong and rigid in build.
2. The Deering Ideal is simple in construction.
3. The Deering Ideal is light in draft.
4. The Deering Ideal binds every bundle.
5. The Deering Ideal is a handy machine.
6. The Deering Ideal has more good points than any other make of harvester.

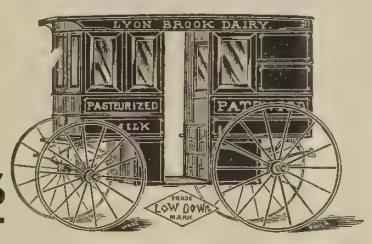
A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.



Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE NEW BOOK Feeds and Feeding

By Prof. W. A. HENRY.
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premum.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

KEYSTONE QUICK HAYING MACHINES.

Keystone Side-Delivery Rake means "Quick Haying, Quality Prime." Turns the hay completely and leaves it in a light, loose windrow ready for loader. Its use means air cured, not sun bleached hay. Better than a Sulky Rake and saves use of tedder. Rakes wide, fast and clean. Takes up no trash, that means clean hay.

Keystone Hay Loader.

Loads the hay from the windrow or cock, or direct from the ground if the hay is heavy. Takes the hay up clean but takes up no manure, rubbish, &c. It makes haying quick and easy. In showery weather it often saves enough to pay for itself in one day. Loads a wagon in 5 minutes.

Keystone Three Feed Hay Press.

Made entirely of steel and iron. Horse power only. Mounted on steel wheels, and stands on the wheels when operating. Write for our special circulars fully describing these machines.

Horses move in a full circle. Each revolution moves the plunger three times—one more feed than any other press made. Requires no more men but increases capacity beyond comparison.

KEYSTONE MANUFACTURING CO., 39 RIVER ST., STERLING, ILL.

This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY AT ONCE.
FITCH CHEMICAL COMPANY, Bay City, Michigan.

A Business Talk.

The great majority of creamerymen this spring will buy some new material for their creameries. It is important that this material shall be of good quality. It will last longer and be cheaper in the end than the average of such supplies on the market. When

FITTING UP A CREAMERY

See that the Vats, Churns, Butter Workers, Tin Ware, Butter Boxes, Engines and Boilers are of the Haney-Campbell manufacture. They cost no more than the other kind, but are of much better quality. Mere mention of these things is meaningless; they must be seen to be appreciated. they must be tried to appreciate their excellent lasting qualities.

Tubular Separators have conquered the world in the matter of clean skimming. They produce a smooth, even cream and have large capacity. They run without the use of a steam engine and have practically no wearing parts.

Babcock Testers are machines that have been made on clap-trap lines until recently. We have a full line of the Elgin Manufacturing Co.'s testers—**No-Tin, Russian** and **Standard.** Send for our illustrated catalogue.

HANEY-CAMPBELL CO., Dubuque, Iowa.

PEAS FOR HOGS
FIELD PEAS
FOR HOGS AND DAIRY COWS
"EQUAL TO CORN AND SIX WEEKS EARLIER"
THE ALBERT DICKINSON CO.
GRASS AND FIELD SEED MERCHANTS, CHICAGO, ILL.

Write It In The Contract.

WHAT SHALL I WRITE?

Just This: "Please ship to me a Sharples Tubular Separator. I will immediately put it into my factory and will give it a fair and careful trial. If I like it in every respect and it does all claimed for it, I will keep and pay for it. If it fails to suit me for any reason, I will notify you to that effect and on receipt of instructions from you will re-ship to your order as you may direct."

We know 'tis a wide open proposition on our part and invites trouble from the unscrupulous creamerymen and the unprincipled separator agents who swarm around every Tubular that is placed, trying by fair or foul means to displace it.

But our faith in humanity is large. Out of hundreds of Tubulars placed on such liberal terms, not a dozen creamerymen disposed to listen to the unholy propositions of competitors, or to take an unfair advantage of our liberality, have been found. A few betray our trust for reasons best known to themselves, but we try to steer clear of that kind.

THE SHARPLES TUBULAR SEPARATOR
Has Merit That Will Win.

It is a hollow bowl separator.
It has no metal bearings except the ball bearing on which it spins.
THE BOWL ALONE REVOLVES.

It is a clean, rapid, superb skimmer of large capacity. The best creamerymen everywhere are using it or about adopting it. Send for Catalogue No. 46.

We are Western Agents for Hansen's Butter and Cheese Color, Rennet Extract, Etc., Etc.

THE DAIRY "VICTOR" Churn.

This Combined Churn and Butter Worker is proving itself to be precisely what the farmers and dairymen have been seeking after. It's work is as complete as the work of the "Factory" Victor Churn, which is rapidly supplanting every other Combined Churn and Butter Worker.

IT IS THE ONLY SUCCESSFUL DAIRY COMBINED CHURN AND BUTTER WORKER ON THE MARKET.

It is easy to handle, easy to clean, perfect in its work, durable and reliable. It charm every farmer and dairyman who sees it work. Manufactured by . . .

F. B. FARGO & CO., Lake Mills, Wis.

There's More Money

in milk than you can get out of it by the old way of skimming. If you had a Victoria Separator you would get *all* the cream—and a better quality of cream—from the milk, in much less time, with much less work than by any other way. It will pay any one who makes butter or sells cream, to write for illustrated, descriptive circular of the

VICTORIA CREAM SEPARATOR

Made in hand and power sizes, adapted to the needs of the smallest as well as the largest dairies. The Victoria Hand-power Separator is as practical, as durable and skims as close as the largest separator made. **Agents wanted.** Write for catalog of dairy appliances—milk coolers, strainers, milk scales, butter tools, etc.

IN THE FACTORY.

The U. S. Takes the Cake.

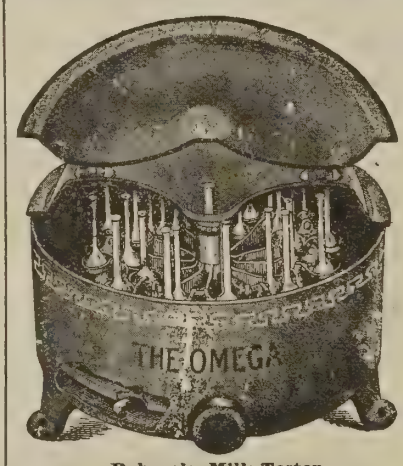
POYNETTE, WIS., Jan. 20th, 1899.

Have been running U. S. Separators since 1892, and can cheerfully say that the new No. 1 Improved U. S. Separator takes the cake. When the skim milk is tested it shows only a trace of fat. I won the sweepstakes and three other first prizes, amounting in value altogether to $115.00, at the 1898 Wisconsin State Dairymen's Association, and all because my No. 1 U. S. Separator makes such smooth, perfect cream.

R. M. BUSSARD, Prop. Bussard's Creamery.

AND IN THE DAIRY.

Very Durable, Very Easy to Operate, Never Out of Order.



TIFFIN, OHIO, Nov. 28th, 1898.

Have used the No. 5 Improved U. S. Separator nearly three years and do not think it is worn a particle. It runs as smooth as the day we first started it. **It is the best separator in the world,** it is so easily run and so easy to clean, and it is always in order to do the best of work. We wonder how we ever got along without one. We think very much of the enclosed gearing. You have the best machine I know of in running and mechanical construction.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

JEFFERSON COUNTY, N. Y., has 125 cheese factories, as well as several creameries.

D. F. SEXTON, of Snohomish, Wash., has a dairy of 21 Jersey grade cows 11 of which are heifers. The production of those cows and heifers, last year, was an average of 305 pounds of butter—another proof that it is not the location, but the men that makes the real difference in the production and profit of this business. The first thing for every dairyman to strive for is, to be the right kind of a man with the right kind of ideas, and all things else shall be added.

Among the many interesting papers which were presented at the last winter's convention of the Wisconsin Dairymen's Association, there were none more timely, or worthy of more earnest consideration by those interested in the cheese industry of the country, than the article found elsewhere in this issue, by a practical New York cheesemaker. The current year ought to witness more than one factory reorganized on the lines suggested by Mr. Cook.

HONOR TO PROF. BABCOCK.

Recognizing the distinguished service which Prof. S. M. Babcock has rendered to the cause of advanced dairying by the invention of the milk test which bears his name, and by other scientific investigations of immeasurable value, the present session of the Wisconsin legislature, has appropriated three hundred dollars for a gold medal to be suitably engraved and superscribed and presented to him. This is a well deserved recognition of the genius and unselfish devotion to agriculture of one of the foremost scientists of the day.

SCOTCH DAIRY JUDGMENT.

The illustration on this page, for which we are indebted to a friend in Copenhagen, Denmark, whose interesting letter in regard thereto, appears in another column, exemplifies better than any words can describe, the inevitable tendency and result of toying with general-purpose ideas and ideals. The awards at this Scottish show are in line with awards at other shows in Great Britain, and in America, too, for that matter, being of a character that would probably command hearty assent from the *Breeder's Gazette*, which, by endorsing "square-endedness" must necessarily accept all that goes with square-endedness, or results from it. It is to such awards as these that the Short-horns owe their dethronement as dairy animals, and if our Holstein friends dally too long with their devotion to a supposed milk and beef form, we fear they will land in the same abyss.

AS TO ADVERTISEMENTS.

HOARD'S DAIRYMAN is continually besieged to give space in its columns for various nostrums, implements and machines, which manufacturers and dealers seek to bring to the attention of dairymen, and induce them to purchase, but its invariable rule in these cases is not to accept an advertisement in these lines that we could not conscientiously endorse in its editorial columns or by personal letter. We cannot undertake to discriminate between rival machines and pronounce *ex cathedra* which is best, but there is no amount of money that can move us to give space for advertisements of "preservatives" or machinery which we do not believe to be fairly well adapted to the purposes for which it is recommended. It follows therefore that we forego a goodly sum of money every week, amounting to several thousands of dollars each year, because of our endeavor to deal fairly and squarely with our readers. If you see a dairy utensil or machine advertised in the DAIRYMAN, it is because we believe it to be at least fairly well adapted for use by dairymen. Such things in the dairy line as you do not find advertised in these columns may, as a rule, be most safely let alone.

A PAIR OF PRIZE WINNING DAIRY (?) COWS.

Winners of First and Second Prizes at the Scottish National Show, the First Prize Winner—the Polled-Angus Cow—also gaining the Silver Cup and Gold Medal as the best Dairy Cow in the Show. Owned and exhibited by Mr. JOHN LOCKHART, Colinton Mains, Edinburg.

SHEBOYGAN COUNTY CHEESE FACTORIES.

They Open Up This Spring Somewhat Earlier than Usual.

The majority of the cheese factories in the county have opened up and are using all the milk they can get hold of. The supply, however, is very limited, and will be for a month or more. The scarcity is due to the fact that nearly all the farmers are raising their calves, which are bringing exorbitant prices. They allow them to run with the cows, and do not expect to patronize the factories until the calves are old enough to take care of themselves. The price of cheese is also 'way up, higher than it was ever known to be before at this time of the year. This fact has caused the factories to open about three weeks earlier than usual, but it is doubtful if they will make much cheese before the middle of next month. Butter, too, is also bringing a good price, which is causing the creameries to get in shape for the season's campaign as rapidly as possible.—*Sheboygan Telegram.*

If it be true, as the *Telegram* avers, that the farmers of Sheboygan county are letting their calves run with their cows, it illustrates very forcibly the decline of sound dairy sense and judgment in that once famous old dairy county. Any man of dairy experience must know that to let a calf run with the mother several weeks will result in serious after loss in the amount of milk that cow will give for the season. A year or so ago, a prominent dairyman residing in Sheboygan county made the statement to the writer that there was much less pride and ambition towards good dairy farming among the farmers of that county, than existed fifteen years ago. He claimed that their cheese factories and farmers both were living on past reputation and caring but little about keeping up to the mark in sound practice, as they ought to.

The report of the *Telegram* would indicate that there is some truth in the Sheboygan man's statement, though we could hardly credit it at the time.

What Is Wanted Is Cows, Not a Cow.

We copy, with full approval, the following communication from Mr. C. I. Hood to the *Jersey Bulletin*. What a cyclone it would have created in the *Bulletin* office if such sentiments had appeared in the editorial columns of the DAIRYMAN, especially any suggestion of the possibility of fabulous records.

Hood Farm is doing a grand work for the dairy interests of the country in establishing a system of yearly records, both of the production of butter and the food required to produce it, and we are very much gratified that Mr. Hood has the necessary influence to secure the publication in the *Bulletin* of such sound doctrine as the following:

I want to express my concurrence in the admirable letter of my brother Jersey breeder, Mr. Gettys, of Athens, Tenn., published in the *Jersey Bulletin* of December 21, 1898, especially when he says:

"In my humble way I have been breeding, feeding and testing registered Jersey cattle for eighteen years, and each recurring year only adds to my appreciation of the worth of any cow that will produce fourteen pounds of gilt-edge butter in seven days. I believe in testing every cow, but think the average standard should be raised, rather than that of the individual cow."

Hood Farm can probably lead out twenty-five greater Jersey cows than the twenty-five best cows shown at the Columbian Exposition at Chicago, and better than can be selected, to the same number, from any other Jersey herd in the world.

But the herd that can show any great number of the phenomenal Club tests referred to by Mr. Gettys, doesn't exist. The cow that will honestly make fourteen pounds of first-class butter in seven days, on non-forcing rations, and is persistent in her large production, is a great cow.

The line of breeding pursued by Mr. Gettys, and the results aimed at, are those also pursued and aimed at by Hood Farm. We are not trying to produce a cow that can be forced into a fancy record, but cows that can elevate and keep up the average standard. Only from such cows come the permanent improvements of the dairies of the country. And our farmers who are testing cows should not be discouraged if it seems a long way from their fourteen pound cows to the fabulous figures which now and then appear. The dairy world, by common consent, puts the stamp of nobility on the fourteen pound cow. In the end, we shall considerably better that average. But do not forget that what we seek is *cows*—not *a cow*.

C. I. HOOD.

Hood Farm, Lowell, Mass.

"If."

If somebody tells you that a tax of 10 cents per pound on colored oleomargarine wouldn't be constitutional, tell him he is ignorant of federal taxation laws—for he is.

If anybody tells you that a 10 cent tax would legalize colored oleomargarine and prevent the state having control of it until after it had passed from the hands of the original receiver in an original package, tell him he is very much behind in his information, regarding supreme court decisions upon this exact point; and tell him further that when oleomargarine has paid a 10-cent tax it matters little how much license the holder has to sell it—it won't be sold when butter is called for. There won't be any profit in it.

If anybody tells you that the attempt to secure this law is useless, tell him that nothing was ever accomplished without effort, and that "can't" never did anything.

If anybody tells you this is "class legislation," tell them that the tax on beer, whisky, wines, tobacco, bank checks, patent medicines and everything else that is taxed is the same kind of legislation.

If anybody tells you that a tax of 10 cents on colored oleomagraarine would be looked upon as an exterminating tax, tell them that Congress placed an internal revenue tax of 10 per cent on state bank notes in 1863 for the purpose of driving them out of existence; but that if butter ever got up as high as 30 cents, oleomargarine could sell with profit even with a 10-cent tax; that if butter were to sell to-day at 4 cents per pound, the two cent tax would be a prohibitive tax on oleomargarine. Few people really understand this question.—*Chicago Dairy Produce.*

Minnesota as a Dairy State.

But a comparatively few years ago this state was noted only for its wheat raising, with some mines in the north and pine in the northeast, but we are hearing it mentioned of late as a dairy state. The cow has come to make us rich as she has several of our sister states. The record we have thus far made for prime butter is unexcelled by any state in the Union, and creameries are starting in every populated county of the state. The grasses for stock have no equal for nutrition and rich milk, therefore when another generation comes upon the scene this will be known as the chief dairy and fruit state of the grand old Union.—Granite Falls *Tribune.*

There is more of hope and promise and value in the two-line statement that the "butter fat" in the milk furnished the Tillamook creamery last year, "brought the farmer an average return of 20.3 cents per pound," than in all the letters read and speeches made at last week's political banquets.—*The Oregonian.*

THE Condensed Milk factory, at Newport, Maine, pays the following price for milk, from April to September per 100 pounds: April $1.08; May 80 cents; June 84 cents; July 84 cents; August $1 08; September $1.08.

A Kansas City police justice the other day fined three milk dealers $500 each, for selling milk below the city standard in butter fat. With one party, it was the second offence and his license was revoked. Extremes often meet. Kansas City has a very delicate conscience on milk, but sends out daily, enormous quantities of counterfeit butter.

Gnats and camels often sleep in one bed there.

THE DIFFERENCE IN VALUE OF MILK FOR CHEESE MAKING.

The patrons of the Barr cheese factory, west of Middaugh Settlement, Alleghany Co., New York, met a few days ago to arrange matters for the coming season. A discussion arose relative to the merits of the Babcock test, when two of the party put up $10 each on a bet that the test had made a difference of 23 cents on a hundred pounds of milk. Oliver Cooley put in 2,022 pounds of milk to the factory, which tested 3.8 butter fat, for which he received $1.00 per hundred. D. O. Jordan put in 1,670 pounds of milk, which tested 4 7 butter fat, and for which he received $1.23 per hundred. Cooley keeps native cows and Jordan has Jerseys. Cooley claims to have won the $10, and the stakeholders think that the whole sum of $20 should be paid into the treasurer.

The decision of the judges, as to the final disposition of the bet money, is about on a par with the objections many have to the Babcock test.

A WISE MOVE.

Mr. J. E. Nissley, Chairman of the Executive Committee of the Kansas Dairymen's Association, in speaking of the next convention of the Association, to be held at Manhattan, Nov. 15, 16 and 17, says:

"This state convention will be distinctly for the farmers of the state. It will embody features of especial interest to the producers of milk. The best ways of handling milk, raising cows for milk, and getting milk on the market, will be discussed.

"In the past, the general tendency of the convention has been to give programs of especial interest to creamerymen, and devices for making butter have somewhat monopolized the attention of the convention. Now, however, we have the creameries all right, and our only trouble is to get milk enough to run them. This convention will endeavor to offer suggestions to the farmers along this line."

Dairy Associations must never forget that the farmer who produces the milk is the chief link in the chain, and that so far as progress is concerned, the whole procession must wait for him.

Every community and state goes ahead in dairy accomplishments only so fast as the men who produce the milk are educated up to the best thought and practice from the farm standpoint.

Whenever we find a community of farmers well posted in cows and cow management, we invariably find that the creamery and cheese factory have to be up to grade also, and both are invariably prosperous.

For this reason our state dairy conventions should be devoted to the cow end of the business very largely.

THEY NEED IT.

One of the DAIRYMAN'S good friends, Mr. E. W. Mosher, cashier of the First National Bank of Aurora, N. Y., sends us nine new subscribers and writes:

"I wish I might make it ninety-nine, for there are that number of dairymen here who need it. They will do the same thing year after year, because it is too much trouble to make the change."

On that point we are reminded of the remark an Irish farmer, not many miles from Fort Atkinson, made to us a year or so ago. We had had some conversation together two or three years before and he had complained bitterly about the fact that he could make no money with his cows. We ventured to say this:

"Mike, the trouble with you is that you have got a lot of poor cows and in addition you are not showing the best kind of dairy sense in the way you feed them. Your main reliance is timothy hay, and that is the poorest milk fodder I know of, while at the same time it sells the highest in the market. You should change your cows and your methods, Mike. Put up a silo and feed your cows in a way a sensible dairyman ought to who knows what he is feeding for."

"Well," says Mike, giving his trousers a histe, "that all sounds very nice, but, dang it, I'm too lazy to take on new troubles." Then with a mischievous twinkle in his eye, he said: "Hadn't I better keep on in the old way and make it up in cussin' "

However, Mike did build the silo and make some effort to improve his cows and is not growling or "cussin' " any more.

"NEED WE EVER EXPECT TRUTH?"

The above is the title of a three quarter-column article in a recent issue of the *Jersey Bulletin*, which is devoted to a review of an editorial paragraph in HOARD'S DAIRYMAN of March 31st. Of course we are not advised as to, the "needs" of the *Bulletin*, but answering the query from the article referred to and that paper's general course in controverted matters, we are of the opinion that if one wishes to escape disappointment he better not expect either the truth or fair treatment in its columns. This conclusion has been reached very reluctantly and not without deep regret. HOARD'S DAIRYMAN has no ambition or desire paramount to the welfare of the dairy interests of the country and it recognizes that its contemporaries are not without influence in this direction. The *Bulletin* has an opportunity for doing a very considerable amount of good in its field, albeit this field is not a very large one, but it very often suffers itself to betray the truth, or so becloud it with faint praise or malicious inuendo as to amount to the same thing, in order to cater to the pride and profit of here and there a patron who reports—we quote the words of Mr. C. I. Hood as published in the *Bulletin*—"the fabulous figures which now and then appear" in its columns.

Its present spasm of untruthfulness is in regard to the Babcock test, claiming with its not unusual misuse of words "that it is about time for HOARD'S DAIRYMAN and a few self-imposed (*sic*) 'dairy leaders' to leave off lying about *The Jersey Bulletin's* position in this matter." And then it goes on to say that no one ever heard Jenkins say a word in derogation of the test, nor has any one read in his paper "a line of opposition to its proper use."

It pretends to admit that the Babcock test is all right for use in creameries and cheese factories as an arbiter for dividing millions of dollars in an equitable manner between contributing patrons, and then with singular infelicity claims that it cannot be depended upon to determine the relative or actual butter producing capacity of individual cows!—a very good illustration of the scriptural metaphor of straining at a gnat and swallowing a camel.

Of course the *Bulletin* is not so profoundly ignorant that it does not realize the absurdity of its position, but it tries to hide its shame under the thin mask of a puerile play upon words and behind the fog of abusive language, by saying that "it is a misrepresentation to apply the test to a lot of milk and call the process a butter test; and a man who will do it must surely be short-sighted, demented or crooked."

Call it what one may, the fact remains, that there is no other practicable way of so surely determining the actual butter equivalent of a lot of milk, whether the product of one cow or many cows, as to subject a sample of it to analysis by the Babcock test. When the *Jersey Bulletin* and all breeders of dairy cattle will admit this fact and be governed by it, fewer "fabulous figures" will appear and the cow that can yield milk in one week containing fat sufficient to make fourteen pounds of butter that will score extra in a commercial market, will be accorded more appropriate consideration than she now receives.

REMOVING THE PROFIT.

It is frequently asked why the per cent of fat in milk should change without apparent cause. During a feeding experiment at the Nebraska Station, it was observed that the weather exercised a very decided influence on the fat content of the milk. During this trial there were ten sudden storms and cold waves.

Of these, seven caused a diminished yield of milk. The per cent of fat diminished in five cases, remained constant in four, and increased in one. The cows at the time were warmly stabled.

If such changes happen when the animals are well fed and stabled, what might we not expect with poor food, cold water and stables. The cow can't talk back, if abused, but she can remove the profit from the milk pail, by using the fat to keep herself warm, and in a quiet, yet very thorough way, she does so, looking after her own comfort before the pocket-book of her owner.

Prize Winning Cows at Scotch Shows.

ED. HOARD'S DAIRYMAN:—The enclosed cutting illustrates the kind of cows people "dairy" with in Scotland—at least the kind of dairy cows that win prizes at the Scottish National show. The paper from which it is taken, the best agricultural paper in Scotland, published the illustration without a smile; but the same mail which brought it, brought me also HOARD'S DAIRYMAN containing the portrait of the Storrs College herd, and the contrast between the American ideal and the Scotch ideal, almost made me weep—for Scotland.

If you want a typical illustration to show your readers the cows they ought *not* to have, you might search a long time, and not find a more suitable object lesson.

C. W. SORENSEN.

Copenhagen, Denmark.

Cow Peas and Kafir Corn.

ED. HOARD'S DAIRYMAN:—I was very much interested in L. W. Lighty's description of cow peas and kafir corn. I would like to plant some for forage. Mr. Lighty says that some varieties are heartier in the north; that for ripening the seed, we had better grow the quick growing kinds, and for forage we use the long season grower.

Would Mr. Lighty please tell me what variety to plant; how much of both kinds to sow to the acre; whether in drills or broadcast, and how deep the grain should be put in the ground? N. M.

Bally, Pa.

There are many varieties of cow peas advertised by different firms and some make wonderful claims, but for a soil enricher or forage crop, I prefer the common black cow pea or the black eye cow pea. These are the most common southern sorts, and I can buy them for about $1 per bushel.

The whippoorwill is also a very luxuriant grower. The seeds are speckled; late to ripen. The Ramshorn is a good grower and fairly early. The early black is a very early pea, but poor forage maker. Northern grown seed, as a rule, matures the plants earlier than the southern grown. We can sow them in drills, and cultivate between rows, but it makes extra work.

If friend N. M. wants them for a land renovator, sow broadcast 6 pecks to acre, with 4 to 8 lbs. of kafir corn to hold up the vines, and cover seeds about as deep as you plant corn. If you have a fine warm seed bed, you will experience no trouble to grow the plant. For me it grows like a weed.

Adams Co., Pa. L. W. LIGHTY.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained by some, that the fat in the milk comes, largely, from the crude fat in the food, but ithas been demonstrated that it is not absolutely necessary, for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

CORN AND ALFALFA.

You say "that Alfalfa hay or corn practically supplement each other and will furnish a balanced ration." I am using this with say one-third bran and shorts mixed. Can I omit the bran and shorts, or would it be best to omit the shorts and give say two-thirds (by weight) corn meal and one-third coarse bran with no shorts. By weight they all cost about the same, viz.: $20 per ton. I have the best of alfalfa and my cows get all they will eat of it. A. M. H.

Dona Ana County, N. M.

If you can manage to chaff (cut) some of

the alfalfa to mix with the ground corn and thus distend or dilute it, the bran may be dispensed with. Corn meal is too concentrated for feeding by itself, either with safety or profit.

Omit the shorts altogether.

A VERMONT RATION CRITICISED.

I have a herd of high grade Jerseys and am feeding this ration daily: 10 lbs. hay, 30 lbs. ensilage, 5 to 7 lbs. meal mixed thus: 500 lbs. bran, 200 lbs. gluten, 100 lbs. cotton seed. Will you kindly criticise this?

Passumpsic, Vt. E. L. E.

Much depends upon the variety and quality of the hay. If, as we fear the fact may be, it is timothy, the protein is materially deficient as the following tabulated statement shows:

	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
30 lbs silage	7.92	.39	4.20	.21
10 lbs. timothy hay	8.68	.28	4.34	.14
7 lbs. concentrates	6.27	1 23	2.68	.33
Totals	22.87	1.90	11.22	.68

An equal amount of clover substituted for the timothy would raise the digestible protein to 2.30 lbs., which is about right for cows giving say 20 lbs. milk per day. With timothy hay, we should consider it advisable to add at least 2 lbs. to the grain allowance.

A VIRGINIA FEEDING PROBLEM.

What would you pronounce the best ration from these feeds, to make flow of milk: Clover hay $13 per ton, corn and oats ground together in proportion of 5 bushels of corn to 10 bushels of oats, $20 per ton, wheat bran $16 per ton, cotton seed meal $22 per ton.

Norfolk, Va. I. C. W.

There is but little choice in these feeds in the matter of relative cost and nutritive value, and hence the main point to be considered lies in their effect upon the quality of the product. If butter is to be made at this season of the year, in the climate of Norfolk, we should certainly use some cotton seed meal, as its tendency is to make a butter that will not soften very readily. On the other hand, if the product is to be disposed of as milk, there will be little or no necessity for using cotton seed meal.

We advise trying a daily allowance of about 4 pounds bran, 4 pounds corn and oats and 1 pound cotton seed meal, and all the clover hay each cow will eat.

THICK *vs.* THIN SEEDING OF CORN.

Will we get more protein, and consequently more feeding value, per acre, from corn sown at the rate of one bushel per acre, than from that sown at the rate of 8 quarts per acre? A. H. B.

Despatch, N. Y.

Prof. Henry in Feeds and Feeding, makes the following statement: "When the stockman is seeking the greatest possible amount of nutrients, possible from the corn crop, he will plant the seed so thickly as to choke the ears to about half their natural size." Experiments at the Illinois Station showed that corn planted 24 inches apart in the rows, gave 4,207 pounds of digestible nutrients per acre. When planted 3 inches apart, the yield was 6,218 pounds per acre.

Experiments at the Pennsylvania Station on the thick and thin seeding of corn, showed that there is a decided increase in the yield of digestible albuminoids per acre in thick over thin seeding. There is also an increase of total digestible matter. The thin seeding was at the rate of one kernel every 18 inches, thick seeding, one kernel every six inches.

USE COTTON SEED MEAL.

I have to pay $22 for for corn meal, $21 for cotton seed meal, $24 for Chicago Gluten feed, and bran $17.50. Would like to know which of the concentrated feeds will be the cheapest for me to use in connection with bran. W. E. B.

Fayetteville, N. C.

At the prices named we consider cotton seed meal, if of good quality, much the cheapest, but it must be fed in limited amounts, certainly not to exceed 3 pounds per day, and preferably not more than 2 pounds, and 6 to 8 pounds of bran, proportioning the total allowance to the individual capacity of the several cows to respond.

SWEET CORN HUSKS AND COBS.

Has there been any test made as to the feeding value of sweet corn husks and cobs, the refuse of the canning factories, when siloed? A. C. J.

Blair, Nebraska.

We are not aware of any reports of specific tests with this kind of silage, at any of the experiment stations; and none are reported in Prof. Henry's book on Feeds and Feeding. It is reported, however, that this refuse is preserved in silos at several canning factories, and that it makes a satisfactory and valuable feed.

Will not some of the DAIRYMAN readers who have some accurate knowledge on this question, make a more specific report thereon.

SILAGE AS AN EXCLUSIVE FEED.

What do you think of feeding silage to cattle alone? Is there any risk in feeding as much as they will eat, without any other feed? Our cows are fed on silage alone when they are dry, and they seem to refuse hay. We have good clover hay, feeding it once a day and the silage twice; but they eat very little of the hay. We are now feeding to our milch cows about 30 pounds ensilage, 10 pounds grain daily, being corn and oats, but have now added a little bran and hay at noon, and almost two shocks of corn fodder to the 40 head in the forenoon, when turned out. We are feeding our young cattle, one year old to six months down, as much ensilage as they will eat. Is there any risk in doing that? We have been troubled with blackleg on two head, although being only calves 3 months old, and for that matter are afraid the silage might affect the older ones. My bull seems to drink no water. He is only watered once a day, and then refuses half of the time to drink. Please give us your advice, also what you think of the ration. SUBSCRIBER.

Green Co., Wis.

We consider good corn silage a perfectly healthful food for cows or steers, under the conditions named, equal in this respect to any other variety of food that can be named for exclusive use. But when any demand, other than mere maintenance is required, there should be some additional feed provided, and this should be of a character to meet the demands upon the animal. Ordinarily this extra demand calls for a feed carrying much larger proportions of protein and ash than are found in corn silage. Whether this additional feed should be supplied in the form of concentrates (grain) or roughage, will depend somewhat upon circumstances and the system of feeding. If the animal is fed first all the silage she will eat, there will be little room in the stomach for taking the additional nutriment in bulky roughage, and bran or oats or gluten feed, or something similar should be offered. On the other hand, if the amount of silage is somewhat restricted, clover hay affords an excellent supplementary feed.

A steer or cow at rest and with no demand upon vital energy except the mere maintenance of existing weight, is said to require the following amounts and variety of digestible food nutrients, namely:

Protein	0 7 lbs.
Carbohydrates	8.0 lbs.
Ether extract (crude fat)	0.15 lbs.

The analyses of Wisconsin grown corn silage show that if of good quality, fifty pounds of such silage will contain approximately the following amounts of digestible nutrients:

Protein	0.65 lbs.
Carbohydrates	7.00 lbs.
Ether extract	.35 lbs.

These figures seem to demonstrate that for simple maintenance, where no increase in flesh is desired, or growth, or there is no fœtus to be nourished, or excessive cold to be withstood, or other untoward conditions to be overcome, 45 to 60 pounds of good silage will constitute a very fair daily allowance.

The ration mentioned as supplied to the cows in milk appears to us to be deficient in digestible protein, and the addition of bran was wise. If the corn and oats were mixed in equal amounts by weight, it would require at least three pounds of bran in addition, to bring the protein up to the minimum standard. Or, rejecting the corn and oats altogether, 4 pounds bran and 4 pounds gluten feed would suffice; or 4 pounds bran, and 4 pounds corn and 1 pound cotton seed meal. The bull will drink if he needs water.

A KENTUCKY CASE.

Please say what, in your best judgment, I should plant for benefit of seven Jersey cows, to be fed in winter. I have clover and timothy hay, corn fodder, and for bran and corn meal, I have to pay usually, $13 and $16 per ton respectively. I had thought of putting one-half acre in sorghum. P. H. J.

Donerail, Ky.

We do not think it expedient to bother with the sorghum, but would prefer to try cow peas, both for soiling through the probable summer drouth, and to make into hay for winter use. We also advise a moderate use of cotton seed meal, and special care in saving all the manure. Thirty-five acres of land can often be made to yield a larger net income, than many of the large Kentucky farms now return. Good tillage of a few acres, with good cows, pays much better than many acres carelessly worked, and many poor cows. Expansion may be all right for the nation as a whole, and it seems inevitable, but in farming it is usually better to contract than expand.

But it is important to bring those seven Jersey cows, and all others that may be added, to a strict account. See to it that none are kept that do not yield a good profit.

BUTTERMILK FROM SKIM MILK.—SILO.

I promise my cows to build a 100 ton silo this summer, and want to know from you just how to build it.

I need a cream separator, but am told skim milk will not make good quality of buttermilk. I sell 10 to 20 gallons buttermilk every day at 10 cents per gallon, and if cannot make good buttermilk with separator skim milk, I cannot purchase. W. A. J.

Osceola, Ark.

On page 187 of the current volume of the DAIRYMAN, you will find a detailed description of the construction of the stave silo.

Buttermilk, of excellent quality, can be made from separator skim milk, if the proper methods are used as to handling and ripening the skim milk.

Ripen as carefully as you would cream and churn when it has just clabbered. If you wait till it is sour it will make the casein hard, and it will separate from the whey in hard clots.

REFRIGERATING ROOM—MILK TRUST OFFICERS.

In building a refrigerator room for cooling milk and cream and bottled milk, where floor is concrete and one wall is brick, does insulation need to be as good as where wooden floor and wall are found? Does concrete floor need any insulation?

2. The names of milk trusts in American cities and their secretaries. Also the names of large milk companies in Chicago, New York and Philadelphia.

A refrigerating room should be insulated by air spaces and wood on all sides and floor. Otherwise the loss of ice is very large. A concrete floor will waste a lot of ice, as it is a good conductor both of heat and cold.

We have not seen a list of the officers of the milk trusts and cannot say where one can be found.

HYDRAULIC SEPARATORS.

There is offered for sale in our town a separator called the Hydraulic Cream Separator, price $10, manufactured at Centerville, Iowa, which they claim will do the work as well as the power separators. Do you know anything in regard to them?

Odell, Ill. SUBCRIBER.

The so-called hydraulic separators do not fulfil the claims made for them. The process of adding water to milk for the purpose of improving the creaming, was given a thorough trial over ten years ago. Recent work by the experiment stations has only confirmed the former verdict, that the process is not so good a method of creaming as either the common shot gun can or shallow setting. If you want to try the process, there is no patent to prevent your using a shot gun can and diluting the milk with water before setting. But you will find the results disappointing, except in the case of milk from cows far advanced in lactation.

FENCING THE BULL LOT.

Will you please tell me how to build a fence about a yard for a bull to exercise in and have him safe. You said at Burchard Farm there was a half acre lot where the bulls were turned each day. I thought perhaps you used some kind of wire fence but as I don't like to take any chances with a bull, I come to you for help. A. G. T.

East Eddington, Maine.

With the exception of a part of one side and end where the yard for the bulls adjoins the cow yard and a short lane leading to the pasture, the fence at Burchard Farm is made of ordinary barbed wire, but with more than the usual number of wires. Where the lot comes adjacent to the lane and cow yard a tight board fence, about 5½ feet high is used.

This arrangement has proven satisfactory for several years but we may have been exceptional fortunate in the character and disposition of the animals to be restrained. In the first place, there have been no bulls on the farm that were not raised there from calf-hood and subjected to kind discipline every day, and never given any opportunity to exhibit their strength or cunning or perverseness. They are always led with a staff, never driven or "cornered" or otherwise given any "advantage". We have no doubt but that some of the woven wire fencing which is advertised in the DAIRYMAN would be equally efficacious and require less attention than one of common wire, which allows the bulls to get their heads between the strands and loosen the staples.

FROM A RECENT SUBSCRIBER.

I have a cow, now five years old, that has been giving milk over three years (has never been dry); has raised three calves, present calf is six months old (not weaned) and she is due to calve again in July next. Which would be better, to dry her up a couple of months before calving and give her a rest, or continue milking her?

What would be the best feed for the calf when taken from the cow? (Intend keeping it for a dairy calf.)

How many pounds should a gallon of whole milk weigh? MRS. J. D. B.

St. Francisville, Ills.

If the cow will dry off easily, we should give her the two month's rest, but if with reduced feed, and milking once a day, she does not incline to shrink quite readily, then continue milking and generous feeding.

We fear the calf has been materially injured by the extra privileges accorded to it. A fattened calf does not usually make a first-class dairy cow. Just how to proceed now is not an easy problem. Teach the calf to drink milk if you can—and this is possible with sufficient patience and courage. It may be necessary to let it get pretty hungry, and let it mourn for its mother before it will accept any substitute for the way it has been accustomed to.

Or you can let it run for a week or two with the mother in pasture, taking away most of the milk, and thus forcing it to follow the mother's example and eat grass, and perhaps a little grain.

A gallon of milk weighs approximately 8.6 lbs.,—or say 8 lbs. and 10 ounces. The richer the milk the less it weighs, but the difference is too slight to be detected by ordinary scales.

The Relation Between Patron and Maker.

[A Paper by Mr. H. E. Cook, of Denmark, N. Y., at the Wisconsin Dairymen's Convention, Feb. 17, 1899.]

INTRODUCTORY.

I feel, Mr. President, somewhat embarrassed coming to Wisconsin to talk about cheese matters, or, in fact, anything connected with the dairy business, because we know that you people, through some of your most prominent citizens and through your dairy school, have given us some of our best thoughts and ideas in regard to the dairy business; and today wherever the dairy language is spoken—and it is spoken in pretty nearly every hamlet in the civilized world—Wisconsin, through its dairy leaders, has come to be known, and I say again that I feel some embarrassment. A redeeming feature, however, is that some of these good men first saw the light in the State of New York.

The little talk I am about to make is more from the business side than from the technical side of the cheese business. I have been interested in dairying and the cheese business all through my life, and I believe that there are two points more essential to do than anything else.

The first one you have already listened to from Mr. Decker—that is the curing of the cheese; and the next is the selling of the product. Whether you may agree with me or not, I believe that is true.

Dr. Jordan, at a meeting recently held in New York, made a statement something like the following, and it comes to that point. A cheese, and a very good one, stood upon the table—Gov. Hoard had a piece of it—and Dr. Jordan says: "What is that cheese good for, no matter what the quality, until it is turned into money? Good for nothing, has no value at all."

In New York state and in Wisconsin too, we have spent a good deal of time and a good deal of money through state aid, to help the cheese maker, and I tell you in New York State we have wonderfully changed the product. We have made the product more uniform and a good deal better; but there has not been any aid in any way given to the business side of cheese making, the selling of the product, only as it has come through individual effort. That is why I place so much stress upon the business side—the disposing of the product after we have got it. You might have cheese which will score 98 to 100 points, and still, without a business man to handle those cheese and get money for them and get them to the consumer, those cheese will have lost at least a part of their value.

Premises must always be right for correct reasoning.

It is for this reason, therefore, that we wish to outline some of the conditions that surround our cheese interests today. Rapid changes are taking place in every branch of trade. A class of goods that was marketable ten years ago, is out of date today. Business methods that were successful then, result in failure now. A cheese that was marketable at that time, is not satisfactory today.

Competition has very materially and wonderfully modified our demands. Some eighteen or twenty years ago we were in control of the export trade through the port of New York. Today the metropolis is practically out of the export trade; we exported 150 millions of pounds, now it is 30 millions. Have the English people stopped eating cheese? No. They have gone elsewhere for the goods, and we suffer accordingly.

Personally I have met and experienced many failures and disappointments, but never once has success or satisfaction eventually resulted by brooding over the past. Let bygones be bygones, and meet the future face to face with a firm determination and renewed energy. This idea carried out is the basis of all success, and let me say, that such must be our policy in the production of cheese, or failure is stamped upon the enterprise.

It is to some of the causes that have led to the present embarrassment and to an apparent solution of them that we wish to call your attention. It is an unfortunate fact that milk producers rarely take the initiative or aggressive stand, but on the contrary are compelled to adopt and maintain advanced methods by individual or corporate business enterprise, or as in some extreme cases, the State Department, under and through its police power and force, is necessarily obliged to interfere in the name of health, and improved sanitary conditions are demanded and enforced.

I have been firmly convinced for several years, that the future American success would depend upon our home markets, and not upon export demand, and in a business way we have acted accordingly.

When we realize that our consumption is only about three pounds per capita, and the English fully six times as much, it would seem to the most casual observer that our home markets offered much the greater opportunity for development. With this idea in view, I began a study of the wants of the customers. A failure to do so has been a general fault with the producers. While manufacturers of most goods are constantly laboring to meet demands, cheese makers have, either by negligence or necessity, ignored the consumer. The only factor with whom he comes in contact is the local buyer or agent.

I wish here to make an assertion, a delicate one, and upon which our good cheese friends may consider me heterodox. It is this: The country dealer does not truly represent the ideal demands of the consumer for the following reason:

Every dealer looks carefully to his own interests first. He has an investment that must be guarded. He knows by experience that transportation and heat will materially affect a cheese, and his only safety lies in a cheese so closely knit, that it is not easily affected. In most instances, this kind of a cheese does not please the consumer, simply because it is not soft enough, or as the consumer terms it, "not rich enough," a misapplied expression, because two cheese may carry an equal percentage of butter fat, and still be of an entirely different texture and make up.

With all, I want to say a word of praise for the local dealer. I have frequently stood by in our large city stores, and observed the cutting and sale of cheese. Did you ever observe that most buyers cut off a piece and taste before ordering? Why? Because there is no recognized standard of quality that can be depended upon, equally by the retailer and the consumer, and they are at all times jealous of the product. If the consumer were to establish a score card, it would be very much modified from the present accepted 50, 25, 10, 15 points. He would score about as follows: Richness 80 points, flavor 20 points. That seems ridiculous to the expert, so called, but here is the point upon which hinges the possibility of increased consumption of American cheese by Americans. Mark my word, not until the makers fully comprehend this point, will the maximum limit be reached.

From this standpoint, and with such a purpose in view, not only upon paper, but in every day business, I wish to make some practical deductions upon the subject assigned to me, viz: "The Relation of Patron to Maker."

What is the trouble we cannot manufacture a cheese of this type? Are we not able to get skill? Yes. Are not the factories equipped to cure these cheese? Not many of them. Is the milk good enough? Here lies the serious trouble.

I was discussing this subject not long since with dealers in Buffalo and Rochester, as I have frequently done in other of our large cities.

In every instance they told the same story. We must have a softer cheese, and when we get it there seems to be no limit to the demand. I asked one of these firms to show me a sample which would exactly suit their trade. The gentleman hesitated, and finally confessed that they did not have such a sample in stock. Said I, "Why don't you buy only such stock as suits your trade?" Said he, "This is not easily done. When we get a satisfactory line of goods, when we least expect it, the quality goes off. In other words, we fail to get uniform quality."

This gentleman was very free to confer with me when he found out I would try, at least, to produce such stock, and at once asked the price. I very politely informed the gentleman that the price would certainly be high enough, to which he had but little objection, providing the quality suited.

This one illustration will suffice for many which might be duplicated many times over in my experience.

We have just passed over a year most trying, with prices abnormally low. Yet this class of cheese has been in demand, beyond the ability of the manufacturers to fill, at from one-half cent to one cent above market prices. To carry out such a plan means that many radical changes must be made; that the present relation between patron and maker must be transformed into one of more thorough unity, either by mutual agreement or by force. I have been carefully studying the milk interests of our state for some years and have observed a gradual change from loose methods to more careful attention to stable management and the care and handling of milk.

Do you know that the cheese interest is at the bottom of the list in this respect? It is not pleasant to realize this statement as a fact, but is it nevertheless unfortunately true. Why is it we have not followed this change? Because our system is wrong.

The plant has but little value. The cheese are made by one man, sold by another, checks signed by another, and many times none of them have any material interest in the business.

How long could any other trade stand up under such management?

You may put it down as a certainty that the cheese business will sooner or later give up to the new order of things.

The manager of the factory must first of all be a good business man, a man of affairs, familiar not only with the details of manufacture, but with the trade with which he is constantly engaged.

Whether or not we shall be able to bring about the desired results under the present patron system, I am not sure.

The result will be entirely dependent upon the personel of the factory management and his relation to the patrons. I am satisfied that milk producers will never take the initiative and demand a system such as we will try to outline, and one that we are now making an effort to carry out in our factories.

Two primary reasons seem to exist for the lack of courage among those progressively inclined, viz: The fact that however much they are inclined toward improved care of milk, they know the neighbor across the way will not, of his own volition, do anything of the kind. And there is very little encouragement for a man to take extra care when his slovenly neighbor delivers milk for which he receives equal returns, and he has no anxiety for its condition; and secondly the factory manager makes no special effort to distinguish between the two grades, thinking the good milk would improve the quality of the poor, and an average would be the quality of the two lots.

I have often heard bitter complaints made against dealers in country produce, on account of insufficient discrimination against the inferior, placing but slight variation in value between first and third grade quality, the first grade being discounted and third grade receiving more than its full value, but the average price making a safe business venture for the purchaser. The same principle is daily carried out in our cheese factories and creameries.

What profiteth a man to produce 4% milk when it returns him no more than 3½% only so far as it improves the value of the whole pool? And what profiteth it a man to produce milk of a high character so long as Smith, Jones and Brown refuse to do so and the manager refuses to compel them to do so?

Withal, our much boasted factory system of the year 1899, with millions of dollars in-

Not a Preservative but a preventative. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION MILK COOLER-AERATOR. It does its work perfectly and its use doesn't violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

vested, is yet crude when viewed from a standpoint at once practical and up to date, as compared with most business concerns, and when subjected to a keen analysis.

So far, we have confined ourselves to a diagnosis of disease. Let us now consider something suggestive and remedial.

Did you ever think that success comes only by one's ability to apply? Many men are wise in means and methods, yet blank failures from lack of ability or courage to apply their knowledge to practical ends.

Most factory managers know well enough the quality of milk needed and the factory surroundings necessary, but fail to apply the knowledge.

There are to-day two distinct systems in factory management which makes for an entirely different relation betwecn patron and maker.

In general, the patron plan, so called, is followed, but rapidly increasing is the purchase plan, paying for milk at a price fixed at least once a month in advance and in some instances a year in advance. This latter system is the direct result of the milk shipping industry, and has many features to commend itself. From the fact that the farmer realize a fixed value for his product, in consideration of which he complies, whether willingly or not, with rules and regulations for the care and handling of the milk, which are found necessary for the buyer, in order to realize a reasonable profit on the first cost of the goods.

Do you realize the difference between a responsibility that guarantees a fixed value, and one like the patron plan that does not?

The factory equipment must be more complete, conditions under control, more money invested, and a larger working capital at hand to tide over unfavorable conditions. There will necessarily be little direct sympathy between patron and maker, but results satisfactory are obtained by compulsion. My purpose is to carry out this system and apply it to the so called patron plan, thus insuring the benefits and results of the purchase plan, without its attendant danger and loss.

How shall we do it?

The maker must be a student of human nature, alert, active, with keen perception, and cognizant of the fact that no two human beings are just alike. The man who takes in the milk must have a keen sense of quality, must know the flavor of milk in its varied conditions, and be able to gentlemanly reject that which is not up to his standard of quality, or rather character. As fine cheese can be made from 3½ as from 4% milk, for reasons patent to any man who understands milk.

This man should possess tact as well, ever attendant upon the wants of his patrons, and yet with all of these good qualities he cannot reach the source of 75% of factory trouble. Why? Because the trouble is distant, is at the farmer's home, and cannot be controlled by electricity.

After some study, the only feasible plan that suggested itself to me was, that system of inspection followed by our condensed milk companies, viz: of inspecting the dairy and the surroundings as often as necessary by a competent man, looking carefully to it that the rules and regulations of good food and care of the animals, good aeration and proper cooling of the milk should be properly carried ont. I am inclined to think we have in the past underestimated the necessity of cooling milk for cheese making, placing too much value upon the aeration alone. I could note many instances where trouble has been averted by aeration and subsequent cooling, simply because germ life has been held in check and not permitted to develop.

In our factories we are now using an aerator and cooler combined, giving us the advantage in the winter of aeration, which is so necessary, and of the combined effect in warm weather. There are several styles on the market, each one a modification of the other, yet the principle in each case is the same. We are now getting down to some system, of which most factories are void, and the following rules are carried out:

1st. Cows must be fed upon good wholesome food and have plenty of pure water and be kept clean.

2nd. All milk must be removed at once from the stable and aerated and cooled in a good pure atmosphere to 70°, and in the winter it must not freeze.

3rd. Milk from diseased animals will not be accepted.

4th. All decomposing matter on the farm must be buried.

5th. Milk will be paid for according to its fat contents.

6th. Milk will not be accepted in old rusty cans.

7th. Whey shall be removed at once from the cans and the cans rinsed and scalded.

8th. The inspector shall enforce the same rules of hygiene and cleanliness at the factory as are required at the farm.

9th. In consideration of the above rules we guarantee more than market prices for the product manufactured.

That reads well and appears well on paper, but paper is worth about 2½c a pound, and that will be about the value of the rules and regulations unless enforced, which I am satisfied can only be done through the agency of a competent inspector, who shall be brought into daily contact with the producers who permit whey to stand in the cans from two to four hours, who wash the strainers in cold water and are otherwise unclean in the surroundings.

No business can succeed without a regulated system, and that enforced.

I am now anxious to have you go with me and discuss a system which I have never seen in operation, but which we purpose to attempt, at least, to carry out, the coming summer, which I trust you will agree with me has some merit in theory, if it does not carry any in practice.

The by-product, whey, is a much abused substance. It receives little care either at the factory or farm house. By analysis it contains one-half of the total solids of the milk and these same solids, so far as they are retained in the whey, are just as valuable for feeding as they were when in the original product. The loss is occasioned only when decomposition and putrefaction enter in, break down and destroy these solids. The sugar of the whey constitutes nearly 80% of the total solids. This sugar, in the usual process of Cheddar cheese making, is rapidly converted into lactic acid even in the cleanest receptacle, and soon loses in feeding value.

In the factory system the whey goes into a vat none too clean, and allowed to stand until the following morning, drawn home and turned into a dirty, sour barrel or vat, and then we proceed to make pork and swear. What is the matter?

The system is wrong. This is the reason that farmers used to denounce it as no better than canal water—which illustration has been discarded since the recent appropriation, for the water is now even richer than whole milk. This condition is the reason why farmers sell the whole product for the same price obtained for the cheese—because they actually realize but little from the by-product. I have spent some time during the last six months studying the value of skim milk and whey for manufacture into articles of commerce, and am yet unable to find an outlet from which more profit can be realized than by a wise, judicious and economical feeding of these by-products in their pure, sweet, original condition, to young growing animals. Many difficulties present themselves at first, which soon disappear after careful reflection.

My plan and purpose is this: To feed the product at a suitable distance from the factory, conveyed thither by means of water pipes, that can be easily flushed and sterilized each day after use, feeding the whey at once after it has left the vat, in its sweet, best condition.

The animals to be fed shall be purchased and charged to the whey account. All feed purchased shall be charged to the same account, together with labor required for feeding, selling and care. When sales are made they shall be placed on the credit side, and at the close of the season, or at suitable times, a balance shall be made and a dividend declared upon the same basis as we now declare the dividend on the milk for butter and cheese sold. This system will do away with hauling the whey back to the farms and the attendant labor of handling it there, which is always crude at the best; do away with the marketing of the pork or young stock, and put it under the care and management of a skilled man; creating a market for the product very much as we now make a special market for our butter and cheese.

I am confident that this system carried out by a good business man will increase the value of the by-product above its present value in a greater proportion than the present method of handling of milk augments its value above what could be obtained if each patron individually manufactured and disposed of his own product.

But I have not yet mentioned the essential element of success in this system, viz: Keep the whey out of the cans and washing them at the factory where every convenience is at hand for cleansing and sterilizing. We had occasion this past season to handle milk from a neighboring factory that had produced the black or rusty spots in cheese. All that I wish to say at the present time, concerning it is this: We produced from the milk, without a single exception, a fancy cheese in every respect. But the cans were frequently sterilized as a possible preventive, and I must confess my surprise at the odor from these cans that were to all appearances thoroughly cleansed at the farm house. Subsequently we sterilized with live steam many cans for a few minutes, and without exception from each and every can where the tin was at all worn or eaten off by sour whey, we found an objectionable odor arising. New cans were invariably all right, but farmers will not buy new cans every year, and the hauling of whey very soon reduces a bright new can to one old and unfit for use.

The appliances at the farm house are not such as to warrant germ free cans, even when the utmost cleanliness prevails. When we realize that it requires live steam for at least one minute to destroy these germs and spores quietly resting and breeding on the inside of a rusty can, and that the scalding water from a tea kettle is not sufficient, and that the good housewife who wishes a bright, clean can, after whey has been hauled in it, must resort to a scouring—removing even more tin,—we must begin to realize that under the present system there is a constant lurking menace to good milk, even though the ever watchful and vigilant maker has succeeded in getting clean cows and thoroughly aerated and cooled milk.

Let me say, therefore, in conclusion, that it seems to me present relations between maker and patron must be very materially changed, and, practically, along lines here mentioned, or the cheese business of New York State—I say nothing about Wisconsin—will eventually pass on and out and become a thing of the past.

In other words, we need improved factory surroundings and equipment; an ability to control degrees of heat and moisture; a good business man at the head, familiar with markets and their special demands; a plant running twelve months in the year; a set of rules heretofore mentioned, not on paper

Good Blood!

Your heart beats over one hundred thousand times each day. One hundred thousand supplies of good or bad blood to your brain.

Which is it?

If bad, impure blood, then your brain aches. You are troubled with drowsiness yet cannot sleep. You are as tired in the morning as at night. You have no nerve power. Your food does you but little good.

Stimulants, tonics, headache powders, cannot cure you; but

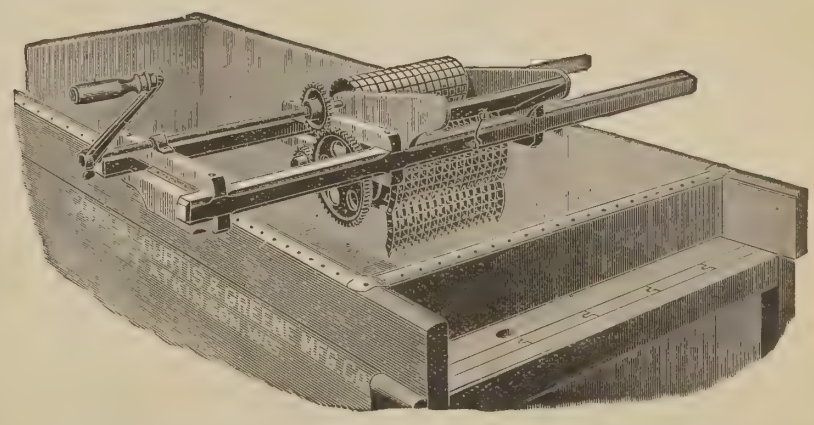
Ayer's Sarsaparilla

will. It makes the liver, kidneys, skin and bowels perform their proper work. It removes all impurities from the blood. And it makes the blood rich in its life-giving properties.

To Hasten Recovery.

You will be more rapidly cured if you will take a laxative dose of Ayer's pills each night. They arouse the sluggish liver and thus cure biliousness.

Write to our Doctors.



We have the exclusive services of some of the most eminent physicians in the United States. Write freely all the particulars in your case.

Address, DR. J. C. AYER, Lowell, Mass.

Do You Want a Good Job?

We can use a live agent in every county. Must have light rig. Money in it. Steady work. Write for particulars. REAL WORTH MEDICINE CO., New Richmond, Wis.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00.

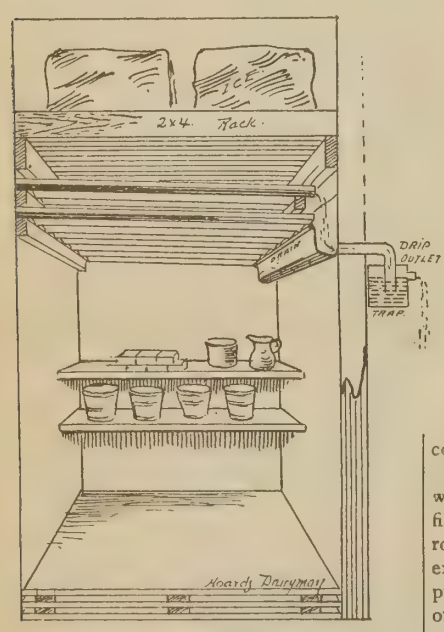
CORNISH, CURTIS & GREENE MFG. CO., Fort Atkinson, Wis.

Inventors, Manufacturers and Dealers in Everything Pertaining to Butter and Cheese Making.

Agents for DE LAVAL ALPHA SEPARATORS.

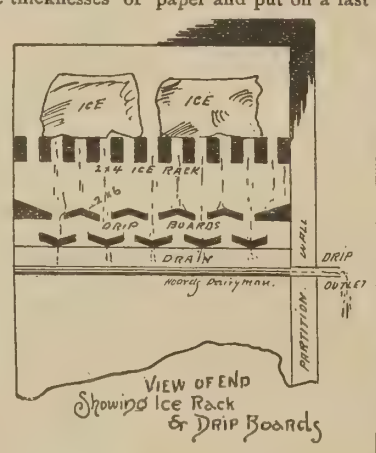
but actually carried out; the sweet whey economically fed and handled; all cans washed and sterilized each day. Then, and not till then, will we have reached a condition of relationship between patron and maker which will bring an increase of "shekels" to both; an actual condition of things such as to warrant the manufacture of the very soft rich American cheese, so much sought after, and so seldom found; a cheese which the American people have given up almost in despair of ever finding, and have educated themselves to the consumption of the soft, so called fancy cheese that require an education of taste to eat them, instead of the good American product that every true American taste demands by instinct instead of education.

Give us these conditions and instead of consuming a paltry three pounds per capita, and searching in vain for an exporter to take the small surplus that weighs down the market and fixes the price of the great bulk of cheese, we should be looking around for new plants and more milk to supply the home demand.



A Refrigerating Room and Other Questions.

ED. HOARD'S DAIRYMAN:—In copy of your paper, April 14th, page 167, you have a cut of Farm Creamery. I am about to build a farm dairy, would like for you to tell me how to construct your refrigerating room and how to operate it; also would you advise me to hang shaft overhead or put it close to the floor? What kind of floor would you advise in this dairy?



I have a small boiler and engine—DeLaval separator. Will have to buy a churn and butter worker. Does it make any difference which way a combined churn and butter worker runs? The DeLaval will have to be turned to the right, and if you put your churn on opposite side of shaft, it will have to turn to the left. W. L. G.

Stonewall, La.

The following cuts and description of a cooling room, by Buff Jersey, are self explanatory:

INTERIOR VIEW OF SIDE

VIEW OF END Showing Ice Rack & Drip Boards

1. The material is to be found in any lumber yard.

2. Any good carpenter can build them.

3. They can be built of any size, from a kitchen chest to a large room for storing butter or working it in.

4. The packages of butter will not take mould, but keep bright and dry.

5. They are very economical of ice.

6. They are readily cleaned.

In 1892, I put a small room in a South Dakota creamery, that would hold 600 pounds of butter. The creamery room was so small that the refrigerator stood only four feet from boiler—a very trying position—but for all of that the temperature was at forty-two degrees. On Springside farm we are using a chest that I built last spring that holds 400 pounds of one-pound prints and 300 pounds of ice. I have often weighed the drip, and when room was up to 96 or 100 degrees, the waste was but one pound per hour. This cooler cost just $11.05 for material, about the cost of freight for a refrigerator from Chicago.

I will give as brief a description of manner of making as possible. For a room of any size, make bottom first of 4 or 6 inch flooring; to start, cut flooring enough for first course—the width the room is to be, and length—take 2x2 inch strips, lay them down eighteen inches apart, and on them lay two thicknesses of best odorless building paper and on these strips nail the flooring; turn the floor over, so naked strips will be uppermost, (the strips are three inches shorter all round than the flooring); now put on two more thicknesses of paper, and lay on flooring flush with strips; cut another set of strips three inches shorter than the floor you now have; lay on these two more thicknesses of paper and put on a last course of flooring.

You now have two perfect dead air spaces, which is a better non-conductor than any filling, and will always be sweet. Inside of room, sides are put on the same as bottom, except at the corners where, as a matter of precaution, I always put an extra thickness of paper, as I add the flooring. In height of building leave enough room over head for ice chamber (2 feet, 6 inches is about right). Now comes the principal feature of the room, namely: the ice racks.

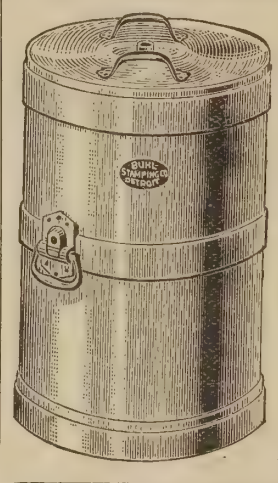
Four inches below where the 2 ft. 6 inch line is from ceiling of cooler, nail securely a 2x4 scantling on long way of cooler, both sides alike; on these rest 2x4's two inches apart. These are the floor of ice chamber.

The ice pans, or drip catchers, are made of 2x6 pine of good quality thus: gouge out one side, like a trough, full width of 2x6, and 1½ inches deep in middle, turn 2x6 over and take off corners, and plane, so the 2x6 will be a gradual fall from centre to edge. These troughs run same way as ice rack. Before placing them, have tinner make a strong zinc or galvanized trough two inches wide, one side strengthened by a wire turned in edge, other side straight; at one end have an outlet pipe soldered on, long enough to go through cooler and project an inch or more; if desired, an air trap is put on end. This trough runs long way of room below ice rack, one end nailed two or three

AMERICAN DAIRY-SUPPLY COMPANY

"Everything for the Dairy."

This Company will distribute Machinery and Supplies, of the highest quality only, through conveniently located agencies. No questionable goods of any kind will be handled. Complete equipments furnished on approved specifications without extortionate charges.



We are prepared to make instant shipments in any quantity desired of the genuine **BUHL and IRON CLAD "Jersey," "Sunlight," "Sunset," "Iowa," "Improved Elgin," "Chicago," "New York," "Philadelphia," and "Cheese Factory" MILK CANS.** The quality of these Cans is famous throughout the world. We caution the trade against inferior imitations of these Cans, without the makers' trademark, offered by Western supply dealers who cannot get the genuine.

Experienced Salesmen Wanted for Kansas and Nebraska.

Address all orders and correspondence to . . . .

AMERICAN DAIRY-SUPPLY COMPANY,

NEW YORK, N. Y. DETROIT, MICH, Or SIOUX CITY, IA.

The Best Factory Cans.

The strong points of the Buhl Factory Cans are their great strength, heavy coating of pure tin, and fine finish. They do not rust like common cans, have no crevices inside, will not leak, and need no repairs. No other cans have the Genuine Heisey Side Handles.

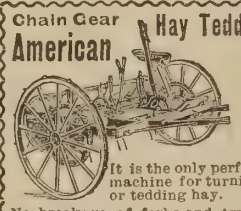
Look for the Milk Can Trademark.

This Can has 3 welded, tinned, wrought-iron hoops, tinned malleable side handles, and heavy XXXX genuine Cookley K cylinders.

Capacity 15, 20, 30, 40 and 50 gallons.

Refuse imitations. We make all patterns and sizes of Milk Cans, and will gladly mail you our hand-book free.

We Make Prompt Shipment.



THE BUHL STAMPING CO.,
Detroit, - - - Mich.

Victor

ANY OLD STRIP OF TIN . .

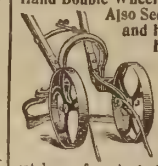
With two nails will fasten the cover. Butter makers who care for the appearance of the package use the VICTOR. Strong and smooth. No tacks or sharp corners to injure the hands. **C. E. Smith & Co.**, Westboro, Mass.

Chain Gear **American Hay Tedder**

It is the only perfect machine for turning or tedding hay.

No breakage of forks and Arms.

STAR PATTERN BILLINGS Planter and Fertilizer



It is the latest, and it drops at twelve different distances.

For Corn, Beans, Peas and Beet Seeds....

If you want them, we furnish Marker and Trip attachment for rowing both ways. Send for circulars.

NEW UNIVERSAL Hand Double Wheel Hoe. Also Seeders and Horse Hoes.

Send for our new 48-page catalogue of our Agricultural labor saving specialties.

AMES PLOW COMPANY, BOSTON AND NEW YORK.

$3.55 buys this all steel Cultivator

complete with lever, five 3-inch shovels, 3 hilling shovels and gauge wheel. Has great leverage with short throw. It is a perfect tool, strong and durable. **14-tooth Lever Harrow Cultivator $3.30.** Sent on "Approval," to be returned if not absolutely the best tool sold at the price. We have complete lines of Carriages, Wagons, Plows, Harness, Twines, Feed Cutters, Powers, and other things at factory prices.

Send for our large catalogue, and save dealers' big profits.

JOHN DORSCH & SONS,
223 Wells St., Milwaukee, Wis.

PRICE IS OUR ARGUMENT.

There is not a manufacturer in America who can compete with us, quality considered. We have for sale

The Best $26. Buggy on the Market.

You have only to pay the manufacturer's profit, the rest goes into the buggy. Do you want a Sewing Machine, Harness or Surrey? Send for our handsome, illustrated catalogue.

Crawfordsville Carriage and Harness Co.,
22 Main St., Crawfordsville, Ind.

inches lower than other to secure quick drainage. On opposite side of room from gutter, secure a 2x4 to lay first course of drip boards, convex side up, and three inches apart; these drip boards rest just over drain, four inches is room enough. Directly under the three inch space, and two or three inches lower down, place concave 2x6s, one end resting on drain, and other end a little higher. You now have an open pan, can see ice every 6 inches, but no water can drop on floor. The drip boards are not fastened, but can be taken down and washed readily. The rack for ice is not fastened, but can be removed at any time. Make doors on same plan as sides and bottom. This room, built as above, will hold the same degree of temperature at all times and is very inexpensive. Outside can be finished with cornice and panel work, if one so desires; put on two or three coats of paint anyway.

With the exception of the jack for the separator, shafting in the creamery is invariably put overhead.

Make the floor of concrete.

Machinery is usually built to run in a certain direction, and separators and combined churns are no exception to the rule. You can easily run your churn the right way by twisting the belt.

DAIRY MARKETS.

ELGIN, Ill., May 8.—Butter offerings 25 tubs, all sold at 16⅜c. Official market firm at 10c.

CHICAGO, Ill, May 8.—Butter.—Creamery, extra, 16c; firsts, creameries 14@15c; seconds 13@13½c; dairies, selections 14c; extra ladles, 12½c: packing stock, fresh, 10@12½c; rolls, 10@10½c.

Eggs—Fresh, at mark, cases included, sold at 11½c.

Cheese—Full cream, Twins, new, good to choice, 9@9¼c; Young Americas, 10@10¼c; Swiss, 10½@13c; Limburger, 7@8¼c; Bricks, new, 8c.

Cattle—The demand was active from all sources, and the general market ruled stronger, with desirable grades of beef cattle mostly 10c higher. Receipts were about 6,500 smaller than a week ago, and combined receipts at the four Western markets were only about as large as the total at Chicago a week ago. The quality was generally good, yet the proportion of finished 1,300@1,500-lb beeves was very small for this season of the year. One load of 1,530-lb steers sold to a New York shipper at $5 45, with $5.35 the next highest, and the bulk of beef cattle at 4.70@5 20, averaging 1,130@1,350 lbs. Corn fed western steers sold at $4.35@5.25; corn fed Oklahoma steers 1,358@1,380 lbs, $5.10@5.30; Missouri-Texas 1,057 lbs. $4.65; native cows, $2.25@4.50; heifers, $3.20@4.95: distillery bulls, 1,562@1,603 lbs. $3.75@3.85; feeding cattle, $3.80@4.90. No straight Texas cattle were received.

Bran—Steady and quotable at $12 per ton in bulk and $12.50 in sacks.

MILWAUKEE, Wis., May 8.—Butter—Creamery—Fancy prints, per lb., 16c; extras 15½@16c; firsts 14@15c; seconds 12@13c; limitations 12@13c. Dairy—Selections, per lb 12@13c; lines 10½@11c. Roll—Fair to choice fresh 10@10½c. Market fairly active and steady, with the quality improving as the season advances; receipts 11,385 lbs.

Cheese—American full cream—October Twins 11½@12c; new, choice to fancy, 9@10c. Brick—New choice 8½@9c. Limberger—Fall, choice 9@10c; winter made, 8@9c. Swiss—Drum, choice 12½@13c; Block, choice 10½@11c. Market declining for new, while supplies of old are about gone; receipts 4,600 lbs and 29 boxes; trade quiet.

Eggs—Fresh per doz 10½c, cases returned. Market unchanged, with a firm feeling, packers taking the bulk of supplies, receipts being 1,047 cases.

AVOCA, Wis., May 8.—Offerings on board were 250 boxes; market firm; all sold at 8½c.

FOND DU LAC, Wis., May 8.—Offerings today were 242 Twins and 290 Daisies; market active, with sale of Twins at 8¾c.

SHEBOYGAN FALLS, Wis., May 3.—Three hundred and thirty-one boxes of cheese were sold on the Call board today, as follows: Ninety-seven boxes Twins at 9c; 184 cases Young Americas at 9⅝c and fifty at 9¼c.

SHEBOYGAN, Wis., May 3 —The sales reported today were 200 boxes of Twins and Daisies at 9c and 300 cases Young Americas at 9⅛c.

PLYMOUTH, Wis., May 2—On to-day's board 400 Twins sold at 9c, 25 Twins at 9¼c, 105 Young Americas at 9¼c, 80 Young Americas at 9⅜c.

SEYMOUR, Wis., May 2—Seymour Dairy Board organized to-day with a small offering of Twins which sold at 10¼c.

NEW YORK, May 8—Butter—Creamery, western, extras, 17c; firsts, 16@16½c; state extras, 16½@17c; firsts, 16c.

Cheese—State full cream, large colored or white fancy, 12; choice, 11¼@11¾c, small fancy, 12¼c.

Eggs—State Pennsylvania and western, 13¼@13¾c.

FULTON, N. Y. May 1—Cheese—Sold here in the past week in small lots at 10½@11c.

LITTLE FALLS, N. Y., May 1—The sales on to-day's board were 52 lots, comprising 2,517 boxes, mostly small cheese; 9c was paid for all but 77 boxes, which brought 9¼c.

UTICA, N. Y., May 1—At the annual meeting of the board to-day, the attendance was unusually large, but few salesmen had any cheese to sell, and buyers didn't offer any definite price. Transactions comprise four lots of large, 283 boxes, and 26 lots of small, 1,550 boxes, all consigned. Total 30 lots, 1,833 boxes.

PHILADELPHIA Pa., May 8—Butter—Solid packed, separator, creamery, extra, 17½c; creamery, firsts, 17c; seconds, 16c. Imitation Creamery, extra, 15c; firsts, 14c; seconds, 13c. Ladle packed, extra, 15c; firsts, 14c; seconds, 13c. Print Butter—Creamery, extra, 20c; firsts 19c; seconds, 18c.

Eggs—Pennsylvania and nearby 13c; western, 13½c; southwestern, 13c; southern, 12½c.

BALTIMORE, Md., May 8—Butter—Market steady. Creamery separator, extra, 19@20c; extra first, 18@19c; creamery first, 17@18c; ladle extra, 14@15c. Western store packed, 11@13c.

Eggs—Market steady; strictly fresh stock, 12c.

KANSAS CITY, Mo., May 8—Butter—Lower; creamery, 12@15c; dairy, 13c.

Eggs—Decidedly firm feeling; fresh Missouri, and Kansas stock in new cases, cases included, 10½c; cases returned 10c.

ST. LOUIS, Mo., May 8—Butter—Steady; creamery, 14@17½c; dairy, 12@14c.

Eggs—Firm, 10¼c.

CINCINNATI, O., May 8—Butter—Quiet, 17@17½c.

Cheese—Firm.

WASHINGTON, D. C., May 8—Market steady, extras, 17c; firsts, 16c.

NEWARK, N. J., May 8—Market firm, 17c for fancy creamery. Receipts moderate.

NEW YORK MARKET.

NEW YORK, May, 6—Butter—Receipts for the week, 37,242 packages. Exports for the week, 673 packages. The market for strictly extra creamery was fairly active. Prices are firm and little stock is going over unsold; but for all other grades, we have had more stock than could be marketed, and we note sales of fine Western Creameries at 16@16½c; most of the state Creameries were sold at the same prices and there is some accumulation of this style butter and prices favor the buyer.

Dairy of finest quality sold at 16@16¼c. but most of the arrivals are off in flavor, or mixed in color, and are salable only at much lower prices, say 13@15c. Imitation creamery and ladle butter were in better supply, quality however is running poor, and prices are lower and irregular. We quote: Creameries, extra, 17c; medium 15@16½c; poor, 13@14c. Dairies, 16½c; medium, 14@15½c; poor, 13@13½c.

Cheese—Receipts for the week, 14,645 boxes. Exports for the week, 7,700 boxes. There was steadier market for new cheese, exporters paying 9@9¼c for large size and home trade taking some small sizes at 8¾@9c. The remnant of old cheese is selling at 10c for finest and 6@8c for lower grades. We quote: Full cream, small, 8¾@9c; medium, 8@8½c; poor, 6@7c. Full cream, large, 9¼@9½c; medium, 8½@9c poor, 6@7c. Old cheese, extra, 10c; medium, 7@8c; poor, 5@6c.

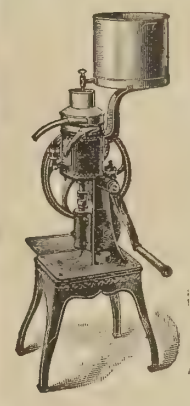
Eggs—Receipts for the week, 83,839 cases. Market is in good shape and strictly fresh eggs sell readily at quotations. We quote: New York and Pennylvania, 14@14½c per doz; Western & Northern Sections per doz. 13½@14c; Southern, 12½@13½c. DAVID W. LEWIS & Co.
177 Chambers St.

BALTIMORE MARKET.

BALTIMORE May 4—Butter—Trading in this article, since our last issue, has shown more animation than for any corresponding time this year, both receivers and jobbers agreeing that the activity on the street reproduced scenes that one time were familiar incidents of spring business, but of late years have given way to the quiet of a strictly distributive allotment of the best parcels of all table varieties to regular customers, whose wants are accurately measured beforehand. There are no inducements, at present, for exporters, so they do nothing beyond sending prices. Out of-town dealers have been able to secure but a very slim share of anything, and then were confined to a few extra creameries, aud some not very good ladles—snap shots at receipts from sources not regular, in the sense that they are ours or anybody's—and have been marketed in every large city east of Chicago, at different times, as the whims of the makers consigned them here or there. There is so little imitation creamery and high grade ladles arriving, that quotations are largely based upon what could be gotten rather than what has been obtained. Roll is in very light receipt, and quality very poor. Ohio and West Virginia are sending in some store packed, solid goods, which we quote below.

Creamery Separator, extras, 18c; firsts, 17; seconds, 16c. Gathered Cream, extras, 17c; firsts, 16c; seconds, 15c. Ohio, extras, 17c; firsts, 16c; seconds, 15c. Imitation, extras, 16c; firsts, 15c; seconds, 13c. Iowa & N. W. Ladle, extras, 14c; firsts, 13c; seconds, 10@12c. Ohio & Indiana Ladle, extras, 14c; firsts, 13c; seconds, 10@12c. Roll, extras, 14c; firsts 12@13c: seconds, 10@11c. Storepacked, extras, 13c; firsts, 12c; seconds, 10@11c. Creamery Blocks, (2 lbs) extra, 19c; firsts, 18c; seconds, 17c. Creamery Prints, (½ lb.) extras, 21c; firsts, 19c; seconds, 18c. Md. Va. & Penn. Prints, extras, 19c; firsts, 17c; seconds, 15@16c.

Eggs—The receipts so far this week have been quite liberal; the demand continues good for all desirable invoices, and up to the present time there has been no accumulation of stock; the demand has been fully equal to the supply; market steady at 12c. Note—As the warm weather is fast approaching, we again urge you to ship your eggs in cases, as they are less liable to become heated, and the loss in breakage is much less than in barrels or boxes. So please bear this in mind, especially those who do not understand how to pack eggs properly.



Cheese—Receipts light; demand fair; market steady. N. Y. State Cheddars, fine, 12@12½c; choice, 11@11½c; fair, 9@10c. Flats, fine, 12@12½c; choice, 11¼@11¾c; fair, 9@9½c. Small, fine, 12¼@12¾c; choice, 12@12⅛c; fair, 9½@10c. Ohio Flats, fine, 11@11⅛; choice, 10½@11c; fair. 8¼@9c. Picnic, fine, 11⅛@12c; choice, 10@11c; fair, 9½@10c. Swiss Cheese, fine 11@12c; cnoice, 10c: fair, 8½@9c. G. M. LAMB & Co.
301 Exchange Place.

FOREIGN MARKETS.

BOSTON, May 6—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as lower, but at the decline in prices the consumption is increasing greatly, and while receipts are increasing of Continental, Irish and home make, there is no accumulations of stock. Danish has dropped to 19@20c, Irish 18@19c. What little American creamery and imitation here meets with a slow demand It is most difficult to realize over 17c for anything in creameries and 16c for imitations. Low grades of butter of all kinds are in light supply, but it is difficult to realize over 15c for anything in ladles, no matter how good they may be. Buyers prices are generally 13@14c. The season is backward, cold nights and only moderate temperature during the day. This has favored old butter greatly.

Cheese markets are all on the downward trend. The free offering of new cheese from America and Canada makes buyers very cautious and their purchases are aggravatingly small, causing holders of old cheese some little uneasiness, and in most cases are inclined to accept lower prices to move quantity. Stocks are not large, but the high price of late has curtailed consumption greatly.

"ALPHA-DISC" CREAM SEPARATORS

The improved "Alpha" disc or divided milk-strata system is used in the De Laval separators only. Strong patents prevent its use in any other machines. The "disc" system makes the De Laval machines as superior to other separators as such other separators are to setting systems. It reduces necessary speed one-half, reduces size of revolving bowl, saves labor and power, enables simplicity and durability, skimming cold milk, running cream of any desired thickness, and insures absolute thoroughness of separation under practical use conditions, which is not possible with any other separator or creaming system.

Send for new 1899 catalogue.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

First-Class brick and American cheese maker wants position immediately. Address "O," care Hoard's Dairyman.

Soja Beans.—For soiling, ensilage and hay. Northern grown, medium early variety $2.00 per bu. Circular on growing and feeding 2c stamp. W. H. STODDARD, Carlinville, Ill.

For Sale—"Brown Bessie Omaha" Bulls. A great combination. GEO. E. BRYANT, Madison, Wis. 13-2

Cooley Creamer wanted. E W. AMSDEN, Ormond, Fla.

For Sale—a grand pure St. Lambert Jersey bull, nine months old. Tested ancestors and perfect show bull No better St. Lambert breeding to be got. WM. ROLPH, Markham, Ont.

Wanted Farm superintendent on dairy farm in Waupaca County. Fine house and pleasant social surroundings. Permanent position on salary. Married man, with experience. Good references required. M. C. PHILLIPS, Oshkosh, Wis. 13-4

Wanted—man and wife to milk 35 cows. Must be speedy and clean milkers. Man to care for cows in winter and in summer to work on farm between milkings. References as to character and ability required. State references and wages. Addressing JAMES B. BUCHANAN, Kendall, Beaver, Co., Pa.

Tamworths, ready to wean, $10 each, or $15 delivered. Hermanville Farm, P. E. I., Canada. 32-52

For Sale—Five Holstein Friesian Bulls ten and twelve months old. Also B. Plymouth Rock eggs for hatching. Address C. W. SCHERMERHORN, Charles City, Iowa. 11-4

Wanted—Man and wife on a farm. Man to do ordinary farm work and woman to cook and do housework. Apply to A. KENNEDY, Supt., Indian Ford, Wis. 13-2

$75.00 will buy registered bull Gerben Mechthilde Sir Josephine 2d, H. F. H. B., born August 28, 1897. Reason for selling, compelled to give up dairying. C. KAHLER, Prairie du Chien, Wis. 11-4

For Sale—"Reta's Parole," 20 months' old, solid color, and standard bred. Fine individual and well behaved. Direct blood of best St. Lamberts and Combination. F. L. GASTON, Normal, Ill. 12-tf

Situation Wanted as general farm manager, by man of practical knowledge of business and all its branches of farming and stock raising. First-class testimonials from last employer. Address "MANAGER," care Hoard's Dairyman. 12-2

Wanted—A first-class man to rent a fine dairy and stock farm within three miles of the city of Janesville, Wis. H. F. KELLER, 251 South Jackson St. Janesville, Wis. 12-4

A good man is wanted, right off, by the MT. PLEASANT CREAMERY CO. at Mt. Pleasant, Pa. One who can make first-class ice-cream in all styles and fine butter. Address immediately. 12-2

For Sale—Holstein-Friesian bulls one year old and over of choice breeding, sired by a Mercedes bull. Also eggs from high scoring B. P. Rocks. I. L. CURTIS, Poynette, Wis. 12 2

I Have medium Soja beans for sale, $2.00 per bushel. W. E. CAMPBELL, Rosemond, Ill. 12 2

Half Rates to Madison, Wis., via the North-Western Line. Excursion tickets will be sold at one fare for the round trip from stations in Wisconsin and Michigan, for trains arriving Madison the afternoon and evening of May 25, on May 26 and for trains arriving Madison before 1:30 p. m., May 27, limited to include May 29, account of Inter-Scholastic Meet, etc. Apply to agents Chicago & North-Western R'y. 13-2

Exceptionally Low Rates to San Francisco, Portland, Tacoma and Seattle, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, from all stations, May 15 to 18, inclusive, limited to include July 15, account of National Baptist Anniversaries. Apply to agents Chicago & North-Western R'y.

Exceptionally Low Rates to Sioux Falls, S. D., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, May 26 and 27, limited to include May 29, account of meeting United Commercial Travelers of America. Apply to agents Chicago & North-Western R'y. 13-2

Exceptionally Low Rates to Louisville, Ky, via the North-Western Line Excursion tickets will be sold at greatly reduced rates from all stations on account of Annual Convention Travelers' Protective Association to be held May 16-19. For dates of sale and limits of tickets apply to agents Chicago & North-Western R'y.

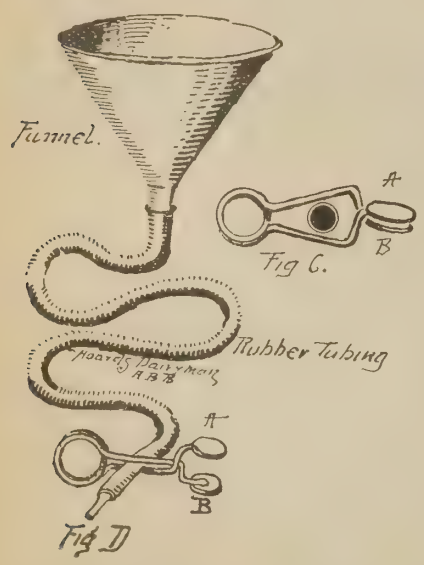
Exceptionally Low Rates to Minneapolis, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, from all stations, May 16, 17, 18, limited to include June 3, account of meeting Presbyterian General Assembly. Apply to agents Chicago & North-Western R'y. sp

Exceptionally Low Rates to Denver, via the North Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, May 15 and 16, limited to June 15, account of Annual Meeting, Cumberland Presbyterian Church. Apply to agents Chicago & North-Western R'y. sp

Half Rates to Milwaukee, via the North-Western Line. Excursion tickets will be sold at one fare for the round trip from stations in Wisconsin, May 15 and 16, limited to include May 19, account of G. A. R. Encampment. Apply to Agents Chicago and North-Western R'y. sp

Exceptionally Low Rates to Roanoke, Va, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, from all stations, May 18 and 19, limited to include June 23, account meeting German Baptists. Apply to agents Chicago & North-Western R'y. 12-2

Half Rates to San Francisco, via the North-Western Line. Quickest time, grandest scenery, variable routes, perfect service. Excursion tickets will be sold at one first-class fare for round trip, May 14-17, limited to return until July 15, 1899, inclusive, account of National Baptist Anniversaries. Apply to agents Chicago & North-Western R'y. 12-2



Parturient Paresis.
(Milk Fever.)

S. B. NELSON, State Veterinarian, Pullman, Wash., before Washington State Dairymen's Association, Ellensburg, Wash.

Could I but say to you, "Your cow has an attack of milk fever, the symptoms of which are such and such, and you must give her this or that drug, which will constitute the treatment," the task before me would be an easy one. This, however, is impossible. The symptoms vary too much, the pathology has required and is still in need of deep study, and this typical western progressive association is too critical.

There is probably no disease in cattle, outside of the category of contagious diseases, which has caused, and is continually causing so much financial loss to dairymen as this one, and I am free to say that it has been a constant source of annoyance and dread to the veterinarian. As a result of this latter unfortunate circumstance, the disease has been the subject of much careful study and investigation by the veterinarians of to-day, who have earnestly tried to elucidate the true pathological conditions of this disease, upon which to prescribe a logical therapeutic treatment.

The earlier writers believed that it was due to congestion of the brain and spinal cord. It was also thought that it was due to air being admitted into the blood vessels. These suppositions were followed by the theory that the blood supply thrown back to the system immediately after parturition was the cause of the trouble. Next we find the hypothesis advanced that the nervous force which has been stored up in the system during the period of gestation, has not been expended during the easy parturition and is therefore returned, which results in the paralysis of the motor nerve endings and thus causing the disease. These various theories carried with them their own peculiar treatment, but the percentage of fatal cases remained large.

Later Schmidt-Muhlheim advanced the proposition that the disease was due to ptomaine poisoning— the ptomaines or toxines being formed in the uterus from the lochia, only in the absence of air, and absorbed by the system. The ptomaine theory has not been accepted by most veterinarians. The source of the ptomaines, however, is still a mooted question. Dr. J. Schmidt, of Kolding, Denmark, believes that the ptomaines are produced from the colostrum cells of the mammary gland and not from the lochia of the uterus. He brings forth in an excellent argument a great deal of evidence against the Schmidt-Muhlheim proposition and in favor of his own.

When we consider that the disease does not occur, or very seldom, in prima para, but in cows bringing forth their third, fourth or fifth calf, in deep milkers, and when they are at their best, there is a good deal of food for thought in Dr. Schmidt's statement. I believe it is the most reasonable of the theories yet placed before us.

The symptoms as we see them are as follows: The animal is taken sick some hours, from six to twenty-four, after the birth of the calf. At first she is uneasy, stamping her feet, switching her tail, etc. Later she becomes dull, then staggers in her stall, at times falling; the appetite has disappeared and rumination has ceased. There may also be a swelling of the udder. Later the symptoms are generally very characteristic, the animal is down, unable to rise, she may be quite comatose, the breathing stertorous, the eyes staring; the bowels have ceased to act and the contents of the posterior part of the bowels is very hard and dry. The temperature may vary greatly, from ninety-five to one hundred and five degrees. Such are the symptoms as they are generally observed. I believe that any of you who have seen a typical case of milk fever will readily recognize these.

The treatments have varied as much as the theories of the cause of the disease, from stimulants, as hot as can be given, to aconite in good large doses to lower the blood pressure, and the most of us have tried nearly all of them with good, indifferent and bad results.

If we should obtain a remedy which may act nearly as a specific, it will not pay us to throw overboard everything that has been used prior to this. That is, there are certain attentions which should be given every patient. She should be placed in comfortable quarters and the surface temperature regulated by means of hand rubbing, blankets, etc. Give her a purgative potion, which may be your choice of either an ounce of aloes in a ball, two or three pounds of magnesium sulphate in a drench, or you may obtain the laxative action from two or three quarts of molasses, given per mouth. Rectal injections of warm water are always of value; they should be repeated. To stimulate the heart's action give rectal clysters of 0.5 per cent salt solution, that is, into every gallon of water dissolve six drachms of salt. In addition, the following treatment has met with favor in the hands of many practioners and with failure in others: Sweet spirits of nitre twenty ounces, aromatic spirits of ammonia ten ounces. Give three ounces of this mixture in one pint or quart of water every half hour until five doses have been given, and then every hour until the remainder has been administered.

Another remedy, which is based on Dr. Schmidt's theory, that parturient paresis is caused by the absorption into the system of ptomaines from the udder, is to inject into the udder through the teats, one quart of boiled water, into which has been dissolved from two to three drachms of potassium iodide, the solution thus formed strained and cooled. Plenty of air should be allowed to pass in with the fluid. After the injection, thorough massage should be applied to udder so as to force the iodide solution into contact with every portion of the gland.

The fact that a greater percentage of cases recover under this treatment than under the others is not the only factor to be taken into consideration, but also the fact that the animal commences to improve from the time of the injection into the udder, and in from four to six hours the comatose condition disappears, and in from twelve to twenty-four hours she is able to stand, while under other methods of treatment, the disease lasts more than twice this length of time, and if the patients are seen early when not very bad, they grow worse before they become better under the old forms of treatment. Out of four hundred and twelve cases reported, ninety per cent recovered. This, for results from a new treatment in several hands, is certainly very good.

In the application of the treatment much depends on thorough cleanliness. The udder must be thoroughly disinfected with a two per cent creolin solution. The instruments used in making the injection, this funnel, rubber tubing and glass dropper must also be well disinfected in a solution of creolin, then the iodide preparation carefully poured into the funnel, from which it runs into the udder through the tubing.

It is to be hoped that these favorable results so far obtained which I have enumerated, may be eclipsed by others more so in the future.

Cedar Hill Jersey Farm Notes.

Spring Feed.—Grass and Clover.—A Promising Heifer.

ED. HOARD'S DAIRYMAN:—To-day we are having some signs of spring, but the prospects of early seeding are not good. Cold, frosty nights with some days when there is but little sign of thawing, is our prevailing weather.

A neighboring dairyman has turned his herd on his blue grass pasture, and by the way they stand huddled in corners of fences to get protection from the cold winds, is not a good sign of liberal milk flow. The only feed they can get is the old grass and a slight hint of green grass to come later.

I find it a great temptation to the average dairyman to turn out to grass from two to three weeks earlier than they should, and another mistake is to reduce grain ration at once. I have found that the best results are obtained by reducing as cows show an inclination to eat less. They will give an ample notice of what they want, and this method will save trouble from any inclination to bloat or scour. Some hay at night is also a good thing for them.

This week we will run a pulverizer over all the grounds around buildings and lanes, sowing a liberal amount of timothy and clover seed. We think this will be preferable to weeds. We have just invested in a grass seed sower that is cheap and good. It is a tin tube, about three feet long, attached to a sack to be carried over one's shoulder. There is a gauge valve in the tube to regulate the flow of seed. The manner of operating is to hold tube in hand and swing in a half circle. This causes seed to be thrown over a space of 20 to 25 feet very evenly.

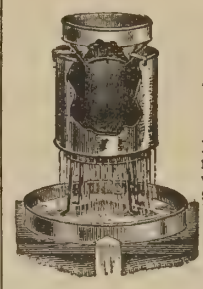
Speaking of grass seed, reminds me that we have about 40 acres of clover to cut this summer, that promises a good yield. We are dressing it with manure, using a No. 3 Kemp spreader. We have spreader set to apply six loads per acre. The loads are nearly, or quite, twice as large as usually hauled on ordinary farm wagons.

Our ensilage is all fed and leaving us to mourn a shrinkage of two and three pounds of milk per cow, in spite of increasing our grain and hay ration. I am fully convinced that we should have silo space enough to feed twelve months in the year. Then when once filled, drouths, long winters, or increased numbers in herd, would not catch us short. If we had a silo full left, so much the better. It is sure to keep and will be good to have in reserve.

Last winter I bought a two-year-old heifer that was only lacking a date or two to make her eligible to record. Thirty-five dollars was the price asked by her owner, who sold her to make room for a dual-purpose cow. This heifer freshened on March 4, giving us a fine heifer calf. She has developed into a phenomenal individual.

She is the best two-year-old I ever had in my charge. She is a beautiful squirrel grey, has the ideal Jersey shape and her udder if photographed would be considered by most people an impossibility for so young an animal. Her daily yield now is just on each side of 30 pounds of milk and tests six per cent full, making over two pounds of butter daily.

I often wonder how my dual-purpose man has invested his $35 to make an improvement on this heifer.



I was fortunate in finding the heifer's mother and lost no time in securing her also. She tests 5.8%, after being fresh since Jan. 1st; is now giving 25 pounds of milk daily. I secured her and her young heifer calf for $50.

"BUFF JERSEY."

Saving the Manure.

ED. HOARD'S DAIRYMAN:—On page 44 of the DAIRYMAN, under the caption of "Land Plaster in Stables," is touched a most important topic. The fertility or plant food contained in the voiding of our dairy cows is,

TESTED BY THE MILK PAIL
Quaker Dairy Feed
SPECIMEN RATIONS.
The rations appearing in our larger advertisements are true and proved. No matter what your roughage, Quaker Dairy Feed can be profitably fitted in. And the same with your feed; it matters little what grain you have grown or what feed you have bought, Quaker Dairy Feed can always serve its purpose as a milk maker. It is profitable in every connection.
Sold only in sealed and branded sacks
MODERN DAIRY FEEDING,
an invaluable book, containing scientifically proportioned rations, including every form of roughage and variety of feed sent postpaid on request. *Scientific Advice on Feeding Free.* Address, Science Dept.,

Parted In A Dream—(New) Pronounced by critics a beautiful song. Very popular. Founded on strange incident of Cuban war. Regular price, 50c. Sent to our readers for 25 cts., post-paid, including also miniature page of DARLING LENORE and MOTHER'S DARLING YET.
Darling Lenore—(New) Is called a very catchy, pretty song with beautiful flowing melody, all in waltz time. Becoming very popular. Regular price 50 cts. Sent post-paid to our readers for 25 cts. with a miniature page of PARTED IN A DREAM and MOTHER'S DARLING YET.
Mother's Darling Yet—(New) Pronounced very pretty. Is extremely popular with singers of lullaby songs. Regular price 50 cts. Sent post-paid for 25 cts., and with it a miniature page of PARTED IN A DREAM and DARLING LENORE.
For 2 cts. I will send one miniature page of each of the three songs. Address the author,
HALBERT L. HOARD, Fort Atkinson, Wis.

or should be, an important factor in the profits of dairy operations.

The great majority of our dairy farms need the fertility very badly, and often don't get it. With me it has been a study for some years, and I tried to profit by the experience of others, as well as myself, and to utilize the findings of our scientific friends at the experiment station. We know that the voidings of a well fed dairy cow, at present prices for commercial fertilizers, if carefully saved and applied to our crops, are worth from $20 to $25 annually.

The first and great loss that we can easily *see* is in the form of liquid leachings, both in the stable and on the yard. About two-thirds of the fertility value is voided in the liquid form, which is much more readily available to plants and, therefore, we should make an extra effort to save that part which contains the most and best fertility.

By carefully cementing our stable floors and gutters and puddling and roofing our manure yards, we can save all the leachings by absorbents. This stops that visible loss, but there is another form of loss that is invisible, but that awful odor in the stable tells the tale if we can read aright.

First and foremost, we want to get rid of that smell, for the sake of our dairy products and the health of our animals, but there is another and very important reason why we should abate that "stink factory."

The great part of that nasty smell is simply the ammonia, liberated from the fermenting manure. Some of us now construct elaborate ventilators and the result is that out of that ventilator shaft a great many of our hard earned dollars escape.

Our careful experiments and investigators, at our experiment station, have proved that if we do not arrest the rapid fermentation and provide a chemical agent to capture the ammonia or nitrogen in form of a gas, we will lose in this invisible gas more than one-third the total value of the manure. Think of this invisible loss from 20 cows, amounting to possibly $150 per year.

Gypsum or land plaster will do this, but it is not the best nor the cheapest preservative. It is necessary to use quite a large quantity, or it will not do the work properly, about 4 pounds daily to each animal, and that costs nearly five dollars per year, and adds no value to the manure, only holds the original value, but if we use instead of plaster, dissolved South Carolina rock or phosphate, one pound per day for each animal will do the work completely and cost us only about $2 per year, and at the same time for each ton of phosphate we use we add 280 pounds of phosphoric acid to our manure, making it a much more completely balanced plant food.

Thousands of farmers use phosphate every year on the land, and by thus using it in the stable on the manure they make *three* profits instead of one. First, they sweeten the stable; second, they hold the nitrogen plant food in the manure; third, they get the full benefit of the phosphoric acid contained in the phosphates. L. W. LIGHTY.

Adams Co., Pa.

The Butter Men are Right.

The butter men have a genuine grievance against the dealers in oleomargarine, who sell that mysterious product under false pretenses to unsophisticated persons, who imagine that what they are buying has been made from cream, instead of from the large variety of articles, which are said to enter into its composition. So long as it has not been proven unwholesome, there can be no valid objection to the manufacture of oleomargarine, or to its sale as such, but there is no doubt, that in this respect, many who deal in it are accustomed to practice a flagrant deception on the public.

Oleomargarine may be all right. It may be as palatable as butter, and equally nutritious. It may even have some points of superiority. The fact remains that not many people, even among those who are ready to admit its innocuousness, and its entire legitimacy as a commercial product, are willing to put it into their mouths. Their unwillingness may be the result of an unworthy prejudice, but it exists, and up to date there has been no getting away from it. As a consequence, dealers in the oleoaginous deceit have contracted the habit of misrepresentation, and the law which requires that oleo shall be exposed for sale in boxes, legibly branded with the word which indicates its true character, has been very generally disregarded.

This makes a two-fold wrong, a wrong to the consumer who gets what he doesn't want and wouldn't take if he knew it, and a wrong to the butter man, whose business is injured by a fraudulent competition. It is now intended to sue the dealers who are suspected of practicing this fraud, and that is what should be done. The state law which prohibits the manufacture of oleomargarine altogether, has been rendered nugatory by the freedom of interstate commerce, as guaranteed by the constitution, and is, moreover, inherently inequitable. The Supreme Court sustained it as a legitimate exercise of the police power, but it has never had the approval of fairminded and intelligent people, and its enactment was a mistake.

It is different with the law requiring that oleomargarine should be plainly marked. That is just and practicable, and ought to be enforced. We wish the butter men success. —*Philadelphia Inquirer.*

Poor Butter in Winter.

One of the causes why the winter butter made in many dairies is not so good and so well flavored as the summer product is that the feed stuffs used are often a little moldy, or in some way spoiled. They may not be "downright bad," or the spoiling so pronounced as to make the feeder willing to throw it aside, but they are often just bad enough to put the milk a little off in flavor.

Another common cause is that the churning is not done frequently enough. This is partly because the milk supply is usually less and it takes longer to collect what is ordinarily regarded in the particular dairy as a churning of cream, and partly because it is thought that, as the weather is cold, milk will keep longer, not being liable to sour or undergo putrefactive fermentation. Neither of these reasons is sufficient for churning any less frequently in winter than in summer. The churning should be done as often, with a smaller amount of cream at each churning if necessary. When cream has been over kept, even though the weather be cold, it undergoes a change which seriously injures the flavor and to some extent injures the grain. When cream, for example, is a week old, as it often is in winter churning, it will have lost considerable of its desirable flavor and often acquires an unpleasant one. If for some reason that appears unaccountable to the butter maker the winter butter does not seem as good as it ought to be, and the winter habit is to have long intervals between churnings, make a change at this point, and churn as often as twice a week, and see if it does not remedy the trouble.—*Homestead.*

AFTERNOONS OFF

Tied down to housework, to the scrubbing brush and bucket, to the dish pan and housecloth, is the condition of the woman who still uses soap in her cleaning. On the other hand the woman who uses Gold Dust has her work all done by noon, does as she pleases in the afternoon. With Gold Dust she does her cleaning with half the effort, in half the time and at half the cost as with soap or any other cleanser. For greatest economy buy our large package.

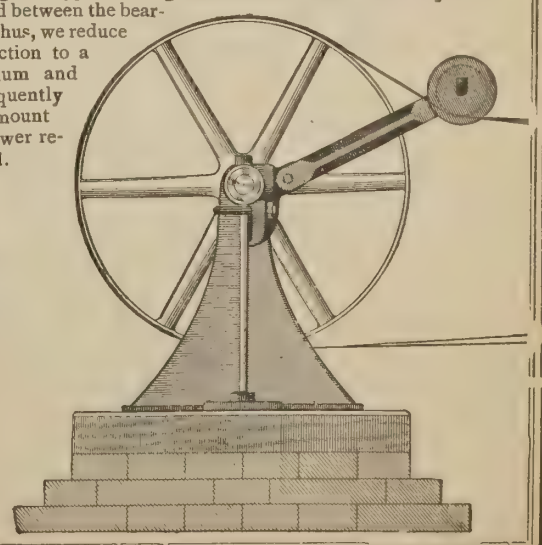
What We Claim for the REID Long Spindle SEPARATOR



Our new Long Spindle Separator and Belt Tightener, when taken together, will run with one-half the power required to operate our old style machine, *and less than half the power required to run any imitating separator.*

It requires practically no oil, the top bearing being frictionless. It requires no special foundation.

There is less wear and tear on the belts and the bowl will keep in perfect balance always.

Our improvement consists in lengthening the spindle and putting the upper bearing above the bowl so that the bowl is carried between the bearings; thus, we reduce the friction to a minimum and consequently the amount of power required.

Our new **BELT TIGHTENER** is calculated to take up all tension in the bowl automatically and consequently operators have no trouble in keeping the machine up to full speed, as the bowl cannot slip.

These Tighteners may be applied to any of the Reid Improved Jacks or the old Danish Weston Jacks.

A. H. REID, 3000 Market St., Philadelphia, Pa.
And ELGIN, ILL.

Preparation of Concentrated Feeds.

HOARD'S DAIRYMAN is in constant receipt of inquiries which call for an explanation of the different feed stuffs which are on the market.

The following excellent definitions of feed stuffs is from an address by Prof. J. B. Lindsey, before the Society for the Promotion of Agricultural Science:

COTTONSEED MEAL.—The seed of the cotton plant as it comes from the gin where the cotton fibre has been removed, is still covered with a coat of white down technically known s "linters." This being removed, the seed appears as black in color, and irregular egg-shaped in form. The thick, hard, black seed-coat or hull is filled with the coiled embryo, (meat) which in turn contains a large number of oil-containing cells. Machines have been invented to remove the hull. The meat is then cooked in large iron kettles, and while still hot is wrapped in hair cloth, and subjected to a pressure of 3,000 to 4,000 pounds per square inch, to remove as much of the oil as possible. The pressed cottonseed cake is cracked, ground, and results in the decorticated bright yellow cottonseed meal of commerce. A ton of seed furnishes about 800 lbs. of meal. Sometimes a considerable amount of hull is ground fine and mixed with the meal, producing a dark colored article, having not much over one-half the feeding value of the prime material.

LINSEED MEALS.—Linseed meal is the ground residue remaining from the flaxseed after the oil has been removed. The larger part of the flaxseed used in this country is grown in North and South Dakota and in Minnesota. The seeds of the flax plant are flattened, elliptical-oval, pointed at the lower end, and of a brown color. They contain in their natural state from 30 to 35 per cent of oil. Twenty to twenty-eight per cent of the oil of the seed is removed by warm pressure. This oil is known as linseed oil, and after being refined is used in the preparation of paints, varnishes, printer's ink, or in the manufacture of soap. The pressed cake remaining is dried, cracked and ground, and furnishes the old process linseed meal. A considerable portion of the old process meal is sold by the National Linseed Oil Company.

The so-called "Flax Meal" is made by the Cleveland Linseed and Oil Co. The oil is quite thoroughly extracted from the crushed seeds by means of a solvent, and after the extraction the meal is treated with steam, which process tends to produce a coarse and flaky product.

Linseed meals are generally known as oil meals. This is an incorrect name, the oil having been to a considerable extent removed.

GLUTEN PRODUCTS.—The various products known as gluten meals, gluten feeds, germ feed and the like, are the residues resulting from the manufacture of starch and glucose (grape sugar) from maize or Indian corn.

How the parts are separated. The corn is first soaked in quite dilute, warm, sulfurous acid water. It is then ground by being passed, with water, through mills to carry off the substance in suspension. Degerminating machinery removes the germs at this point. The germs are dried and crushed through rolls, and the oil pressed out, leaving the residue in cakes. It is largely exported as

CORN GERM CAKE.

After degermination, the suspended mass is bolted through sieves, separating the hull, bran and some light weight and broken germs from the starch and gluten. The first materials (hull, bran, broken germs, etc.) are pressed and dried, and results in what is known as

CHOP FEED.

The starch and gluten are run into concentrating tanks, and then very slowly through long shallow troughs. The starch settles down like wet lime in these troughs, while the hard, flinty portion or gluten floats off into receivers, is concentrated, and finally pressed in heavy filter cloths, run through steam dryers, and appears as

GLUTEN MEAL.

The gluten meal and chop feed mixed together, pressed and dried, constitutes gluten feeds. [See preceding.]

CLASS II.

ATLAS GLUTEN MEAL.—So called, is very different from the ordinary gluten products. The germ is first removed from the Indian corn, and the remainder of the corn kernels are mixed and ground together with rye, barley, wheat, juniper, etc. This product is then heated with a solution of malt, which converts a considerable portion of the starch into sugar. Yeast is then added, the alcohol, etc., resulting distilled, and the refuse remaining in the still is pressed, dried, and placed upon the market under the above name.

DRIED BREWER'S GRAIN is the kiln dried residue from beer manufacture. It consists of some of the starch, together with the hulls, germ and gluten of the barley. A small portion of the gluten and a large part of the starch are removed from the barley by the action of diastase and yeast.

MALT SPROUTS.—Malt used in beer manufacture is prepared by moistening barley and allowing it to sprout. The sprouting produces a ferment called diastase, which changes starch into sugar. After the formation of the diastase, which requires a certain number of days, the barley is dried, and the sprouts removed by machinery and sold for cattle feed. The barley is now termed malt.

CLASS III.—WHEAT PRODUCTS.

The wheat has the same general formation as the corn kernel. The natural divisions of the feed resulting from grinding wheat are bran, middlings and red dog flour.

Bran is the exterior covering, and is first removed.

Middlings are removed next after the bran.

Red Dog is a very low grade of flour, and represents the dividing line between feed and high grade flour.

Flour middlings is a mixture of middlings and red dog flour.

Mixed feed is generally a mixture of bran, middlings and red dog flour.

H. O. dairy feed consists of oat feed as a basis, mixed with feeds high in protein, such as cottonseed and gluten meals.

CLASS IV.

Cerealine feed. This feed comprises the hull, and some of the starch of the corn. It is the by-product resulting in the manufacture of the breakfast preparation known as cerealine flakes. It is very coarse. It possesses a feeding value but slightly inferior to corn meal.

Hominy feed or chop. Hominy is the hard part of the corn kernel. The separation of the hull, germ and some of the starch which constitutes the feed, is said to be brought about solely by the aid of machinery and steam.

Chop feed has been described under gluten products.

Oat feed, corn and oat chop, etc. Oat feed is the refuse from factories engaged in the preparation of oat meal and other cereals for human consumption. It consists of poor oats, hulls and some of the bran and starch removed in the process of manufacture. It is sometimes mixed with corn, as corn and oat chop.

Working Butter in the Churn.

ED. HOARD'S DAIRYMAN:—I saw in your paper about working the butter in the churn and I have tried it, but I cannot get the water or brine out to satisfy my customers. In a tub of sixty pounds, one claimed that there was two pounds of water.

I think the flavor and grain far superior to what I have made before, but that is my one difficulty.

The gentleman who wrote the article said, he had not used the worker for some time, but had worked his butter in the churn. Please explain in your paper, or give me his address, so I can write him. E. J. T.

Bridge Hampton, N. Y.

The way to obviate the above difficulty is simply to exercise greater care in packing the butter. It should be packed very firmly, draining off whatever brine may be pressed out in the operation.

In my own practice of this method of working butter, it has been the rule to turn the tubs or crocks (the latter used for certain private customers, who preferred them) upon their sides, at the time of shipping, to make sure there was no surplus of water contained therin.

It has been found that considerable brine will run out of a large tub of butter, but as by this simple means it can be removed, there is no harm done.

For the benefit of those who may not have seen the previous article upon this subject, I will briefly describe the process again.

When the butter comes to the granular stage stop the churn, and draw off the butter milk. If the butter does not separate freely, add salt, a pint to forty pounds or about that proportion. This does no harm to the butter milk for feeding or culinary purposes, although it might injure its sale. However, it acts like a charm in the churn; a few revolutions of the crank, after it is added, brings the butter globules to the surface, without further trouble. On no account must the grains be allowed to mass; they should be not larger than fine shot.

The first water should be about the same temperature as the butter; the next tempered to 60° or 62° in cold wheather, something depending upon the temperature of the room. Butter from Jersey or Guernsey cows will be waxy, and in fine condition for working at a temperature which would prove injurious to other butter.

Wash twice, drain thoroughly, but do not touch the butter until the salt is added. Weigh or measure the salt and sift a portion

Write for what you want. Visitors always welcome. JOHN E. ROBBINS, Greensburg, Ind.

of it over the butter, turn the churn to expose fresh granules and add more, continuing this until all is added. A roomy churn is required for best results. This is always an advantage anyway.

A large wooden fork may be used to more thoroughly incorporate the salt if desired, but do not remove the butter from the churn. As soon as the salt strikes the globules the brine begins to start, each tiny particle receives its quota over its entire surface. Practically this is brine salting.

Put on the cover, close the lower opening of the churn and revolve very slowly. The exact number of revolutions is immaterial provided the butter is at the proper temperature. It must not show the least sign of being too warm, or the grain will be injured.

At the end of two minutes, there should be one or more solid lumps of butter in the churn and quite a quantity of brine. Remove the cover, hook the churn and drain. With the ladle or fork, break the butter into pieces, replace the cover and again revolve the churn as before.

At the end of another two minutes the operation should be completed and the butter ready to pack. It ought to show a perfect grain with no trace of mottles, either then or at any subsequent time.

Should these appear, it indicates insufficient working and a little more care in evenly adding the salt will be advisable. Motles are the direct result of uneven distribution of salt throughout the butter, the color being lighter where there is little or no salt.

After practicing this method of working butter for a year, I still have no disposition to abandon it. For me, its results are perfectly satisfactory in every respect.

W. C ROCKWOOD.

Genesee Co., Mich.

Not Quite Satisfied With Silage.

ED HOARD'S DAIRYMAN:—There is one thing I would like to ask you. What effect will silage feed have on the cows?

I have several cows and am feeding silage, but I think it ruins their insides in time. Now, the first year I fed silage, the cows liked it and got fat on it, but the next year they did not do so well and I nearly lost one cow, and I think sure it was the silage feed, for she got better in the spring, though it was a hard pull to get her through till the grass was fit for her.

The next year I did not fill the silo. They did well. I fed hay, corn stalks and roots. Have always given bran mash warm at night till lately. Now I feed bran dry, because I think with the silo the wet bran is too much for them.

This year, I filled my silo good, all corn cut when it was just right and the silage looks good. Never had it better than now. Yet the cows don't do well; are never hungry; they will eat it but they don't like it. They will not eat it alone very well, so I cut hay or straw and mix with it, then I put bran and salt on it and so coax them to eat.

I have tried it all ways, with and without mixing it. When I am gone out of the barn and they know they will not get anything else, they will eat it. They don't act like that when I give them corn stalks or hay.

Sometimes they are bound up, then again they scour. With all the care I give them, they will fall off in their milk, and as I am a milk peddler, it is very inconvenient. When I want milk the most, then they give short measure.

Can you or any reader account for it? My best cow freshened this winter and she was quite sick about two weeks after. I gave her two doses of physic per day—the physic prescribed by HOARD'S DAIRYMAN—but it never seemed to physic her any.

I left off feeding silage. She is better now, but not what she was for giving milk that she was before when she came in.

Now I would like to hear of some one else's experience on silage feed. I like the silo, it is handy and cheap. But I do think it wears the cows out. I don't think they could stand it many years. I am always in fear. I never know when they will get sick of it and stop eating. I feed silage three times a day, one-half bushel to a feed, mixed with cut hay. ALBERT EDWARDS.

Charlevoix Co., Mich.

Our Michigan friend's experience with silage is so opposite to our own and that of the great majority of those who have fed it for years with the highest satisfaction, that we are utterly unable to account for the results he reports. Elsewhere in this issue, in reply to a Wisconsin subscriber, we have discussed the silage question somewhat, and there may be a suggestion there, indicating some of the possible causes of our friend's failure to find silage as profitable as others find it.

Fattening Dairy Heifers.

ED. HOARD'S DAIRYMAN:—I notice all dairy writers who have touched on the subject, caution against allowing the dairy heifer to get fat.

My experience leads me to believe the danger to be greatly overestimated, and I believe 99 heifers are dwarfed and permanently injured by underfeeding to one injured by liberal feeding.

Do these gentlemen never turn their growing heifers on good pasture? And, if so, do they never get fat?

My experience leads me to believe that the animal that will not get fleshy on good pasture is lacking in digestive capacity, and will never amount to much in the dairy.

The first really dairy bred heifer I raised was so beefy looking, that on taking her home from pasture, a butcher of my acquaintance tried to buy her for beef, saying she would never amount to anything as a dairy cow because she carried too much flesh. I knew she was sired by a splendid bull and decided to keep her anyway. She calved in Nov. '94, at 22 months, and gave as high as 39½ lbs. in one day, testing 3.3%. Freshening again a few days before she was three years of age, she gave 56½ lbs. in one day, and a little over 12,000 lbs. in the ensuing year. In May '97 she gave 74 lbs. 14 oz. in 24 hours. Last season in spite of a peculiar sickness lasting several weeks after freshening, 60 lbs. in one day, and she is still doing good work in the dairy. She now has the thin drooping neck, prominent back bone, cat hams, and the general appearance of your typical dairy animal.

This cow always had this form, it was simply covered by this surplus flesh, because it was natural for her to do so.

Again, early last summer we had five fine heifers calve, that had been wintered on ensilage mostly, that came through very fat, yet all did well. Feb. 6th a heifer calved that was fat all of the winter of '97-'98, all last summer, and still very fat when she calved, yet she has given 40 to 46 lbs. daily ever since. (April 15th on mixed hay and gluten feed, 46 lbs.). Now that dairy form is uncovered.

In short, if a heifer inherits a tendency to do dairy work she will do it when the time comes, and do it all the better if she has been liberally cared for. Do not scrimp the growing dairy heifer.

Lorain Co., O. GEORGE R. CREHORE.

NEW YORK has decided to have her dairy products placed on the market without the use of those preservatives which are so highly lauded and profitably supplied by the dealers in antiseptics. The Governor has signed the bill, and it goes into effect at once.

The *New York Produce Review* comments as follows:

"The new law strikes a blow at all preservatives excepting salt. The danger confronting our export trade from the use of boracic acid, demanded some legislative protection, and the Empire State was not long in seeing the necessity for immediate action. The expression of the dairy interests of New York State, as well as the merchants of her large cities who handle so much of the product of the country, is overwhelmingly in favor of keeping our butter pure. The preservative people have been carrying whole page advertisements in western dairy (?) papers trying to beguile the creamery managers and ladle packers into the use of their compounds, and the passage of this bill will be a wholesome check to their schemes."

It is to be hoped that the time will come when we can buy our food without the suspicion that it has been "doped" with powerful drugs under the excuse of preserving it from decay.

The Soy Bean as a Farm Crop.

[Press Bulletin.]

A comparatively new and promising leguminous crop for Indiana farmers is the soy bean. This plant has been successfully grown in different parts of the state, and at several points farther north in the United States. It thrives in good corn soil, and will grow wherever corn can be successfully produced.

Being a quick maturing annual, it will prove especially helpful to those who cannot grow clover. A crop of soy beans can be produced betweed the spring and autumn frosts anywhere in the state. The soy bean may be grown for pasture, green forage (soiling), for hay or silage, or for seed. It will yield 9 to 12 tons of green fodder, 1½ to 2½ tons of hay, and 10 to 40 bushels of seed, according to variety, condition of soil, etc.

VARIETIES.

If seed is desired, the earlier varieties, only should be grown in northern Indiana. The medium early varieties will doubtless mature in most parts of the state, and are to be preferred, owing to their greater yield. The later varieties might be grown for soil renewal and soiling, but they would hardly mature seed.

CULTURE.

The soil may be prepared as for corn. If impoverished by previous cropping, the soil should be well supplied with lime, potash and phosphoric acid. Nitrogenous manures have also proved beneficial in New England.

The seed may be sown broadcast with the wheat drill, in rows 16 to 24 inches apart, or with the corn drill to be cultivated as corn. The earlier varieties of soy bean may follow a crop of rye or barley, or be sown in the standing corn at the time of the last cultivation, if the weather is seasonable. If sown in corn, put in two rows of soy beans between each two rows of corn. Sow about two pecks to the acre in rows, like corn, and cultivate, if seed is desired. For pasture, soiling or hay, sow four or five pecks to the acre.

FOOD VALUE.

Soy bean hay compares favorably with clover hay in chemical composition. The seed is very rich in protein and can, therefore, be fed advantageously with corn. The seed should be ground before feeding. The seed is readily eaten. Stock, as a rule, do not relish the stems and leaves at first, but soon take kindly to this forage.

Soy beans and sorghum supplement each other as soiling crops. Corn and soy beans, together, are said to make good silage.

HARVESTING.

Begin cutting at the time of early bloom, for soiling. Cut for hay when in full bloom, and as soon as the pods have formed, for silage.

COST OF SEED.

Seedsmen offer soy bean seed at $2 50 $5 00 per bushel. This makes the cost far too great to justify growing soy beans as a general crop. Farmers are advised to try soy beans in a small way as a special crop, and then grow their own seed, if the crop gives promise of being valuable.

Echoes From the New York Institutes.

Separating.—Ripening.—Churning.—Preparing Starters.—Winter Dairying.

ED. HOARD'S DAIRYMAN:—One of the places where the old cow, her progeny, and other products, receive much attention, is Lowville. In fact, she occupies a front seat at every institute held in Lewis county, whether it be in Lowville, or elsewhere; and is, therefore, most deserving of mention, when we come to remark upon the institute program.

The senior editor of the DAIRYMAN was at Lowville, last winter, but left town before the question box had been uncorked. His address, together with those of S. Brown Richardson and George A. Smith, however, filled it to overflowing.

Some of the questions were as old as the institutes, and to some readers the answers may read like a "twice told tale;" nevertheless they may be of benefit to some "forlorn and shipwrecked brother" which is my excuse for copying them from the report.

Q—What are the best grains to feed our milch cows?

Geo. A. Smith—That is a good question, and we might profitably spend the whole afternoon on it. If the farmers would study it more closely, they would be much better off. The failure to do that, together with the heresy the farmers have of keeping cows from the standpoint of numbers, instead of production, has cost them millions of dollars. Foods produce fat, growth, muscle and bone. To do this, we must have two classes,—one for heat and one for growth, milk and bone production.

It has been found that it required 12% of the feeding energy of corn stalks to enable the cow to masticate them; corn meal creates heat, and the cow gets a double benefit from it, in one sense—but it does not make milk.

If she is to produce milk, she must be fed the elements that are contained in milk. Clover hay contains these elements in nearly a perfect ratio, while oat straw, timothy hay, corn stalks and silage, do not; so we must balance these foods, with those which do contain milk elements.

Milk having a ratio of 1 to 4, the cow, if she is to give milk, must have foods containing a corresponding ratio. This shows why the cow makes the most milk when running in good June pasture, such grass having the same ratio as has milk. The casein portion of the milk nearly all comes from nitrogenous foods, so that, if one feeds nothing but timothy hay and straw, she cannot produce milk, for the reason there is little or no casein element in her food; therefore, she either shrinks her milk flow or else takes the elements from her body to produce it, in which case, she at once becomes poor and thin in flesh.

A cow whose function is to produce milk, will do so, at the expense of her physical condition; but the cow which is of the beefy type, will put the foods that she eats, on her back and refuse to give milk.

So it is first necessary to find which of the herd are the milk producers, then give them all the well-balanced rations they will eat, digest and assimilate. But no two will require the same amount of food, and, it may be, the same balanced ration. You must watch them, and feed accordingly.

Having corn silage, timothy hay, corn stalks or straw, there should be fed with them, oats and peas, or bran, gluten, oil or cotton seed meals. If your hay is clover, and you have silage, somewhat less of the nitrogenous grains may be fed.

Q—Can cream be separated from milk as easily in winter as in summer?

Mr. Rees—I do not think it can unless the cows are fresh in milk; of course, I refer to deep-setting.

With the separator, there would not be much, if any, difference, since the separator of to-day forces all but about two tenths of 1% of the fat out of the milk.

The great bulk of the butter of to-day is from separator cream; it sells for the highest prices in our markets, and more of it is made from a given amount of milk.

Mr. Dawley—One must learn to make butter by the separator. You have a different cream from that of the old way, and more of it.

When we got our separator it broke up all our methods, and, after using it two weeks, we were about to throw it out, as worthless; but Mr. Smith came to our aid and said: "Cool your cream down to 50° as soon as it comes from the machine, for the purpose of hardening the fat globules". We did that, and in less than two weeks, were making *better* butter than we had ever before made.

It was not only better, but there was *more of it*. Besides that, we were able to make the quality the same from day to day.

One must follow strictly the directions of the man who made the separator, just as Mr. VanDuser said one must follow those of the man who made the incubator. Very many fail to do this, which accounts, in part at least, for an occasional failure to make a uniform quality.

Mr. Richardson:—Mr. Dawley, or rather, Mrs. Dawley knows how to make good butter, and they use the separator.

At Gouverneur, there were but few samples of dairy butter that scored up to the hundredth point, but one of them was Mrs. Dawley's.

Mr. Smith—The New York market wants a butter that scores high and one of quick flavor. The high scored butter is the best when eaten at once, but it does not keep as well as does a slower one. That is why butter, made in the old-fashioned way, keeps better. It is a dryer butter.

Mr. Dawley—At Gouverneur, the great falling off in score points was in flavor. Texture, salt and color were nearly all perfect in the great exhibit, but when we came to flavor, down it went. This loss was caused, in the main, by the handling of the cream after it came from the separators and during the ripening process.

Mr. Richardson—Why is it necessary to stir cream at all?

Mr. Dawley—Cream will ripen more rapidly, or, rather, lactic acid will increase more rapidly, where cream is the warmest, which is at the sides or top of the can; so we use a stirer of our own device. It is somewhat like a saucer with the convex side up. To this is attached a long stem or handle, placed in the center, and which reaches up and through a hole in the cover of the can.

Half a dozen times a day we go to that can, lift that stem handle up and push it down just once. That motion stirs every bit of cream in the can more than we could stir it with a paddle in three minutes, because it changes the position and mixes it all up. The top is forced to the bottom, the bottom to the top and the center to the outsides. Then, too, it is all done in two seconds and without removing the cover from the can; thus saving time and keeping outside air away.

Q—How long should we be in churning cream?

Mr. Dawley—I want to be not less than thirty minutes. If we find we are going to get the butter sooner, we cool the cream down. I hear people say that they churn in five minutes, while others say they have to churn two days. One churns at too high a temperature, the other has improperly ripened cream, or churns at too low a temperature.

If you have cream enough, it will pay to churn quite often; say every other day or at least twice a week.

Mr. Richardson—I wish, Mr. Smith, that you would tell these people how you make your starter.

A—At the Geneva station, we have a John Boyd ripening vat in which the cream is kept away from the atmosphere, it being air tight; but you can put your cream into a glass can and keep it pretty nearly air tight. If we make a milk starter, we select a sufficient amount of pure, clean, sweet skim milk, put it away in an air tight can, and, when it has become slightly acid, we put in about two per cent of the starter into the cream, warm it up to about 68°, cover it up and stir it often with a wire stirrer, or one like Mr. Dawley's.

In about twenty-four hours, the cream is slightly acid and is ready for the churn.

A Lady—How long shall we allow our cream to remain on our milk, set in shallow pans?

Mr. Smith—Until the cream is all up, if you can do it and not have the milk sour. Never allow that to occur, but skim it while the milk is perfectly sweet. This allowing the milk to sour, it may be in one pan, be-

fore taking it off, then skimming another while sweet, mixing both samples, then holding them two long, is the main cause of most of the poor butter made by the farmers.

Mr. Miller—Is it necessary to make a new starter every day, or shall we hold over some of that of the day before?

Mr. Dawley—It is my experience that we ought to have a new starter every day, and not hold over the old one, as a woman holds yeast. We then get it fresh, pure and of just the right acidity. If it is held over, it will become too acid. Select fresh skim-milk each morning, for next day's use.

Q.—How should the milk be conducted from the wagon to the receiving can in the factory, for cheeee or butter?

Mr. Rees—It will be best to dump it; the maker can then look into the bottom of the can and see if it is clean or not.

Mr. Smith—I think that the best way. You save the work of cleaning the faucets and conductors, and it can be handled much more rapidly.

AT CONSTABLEVILLE.

Q—Does winter dairying pay here?

A farmer—It pays me sixty cents out of every dollar, I get for it, provided I get $1.00 per hundred pounds of milk. If I get $1.10, it is more.

Mr. Converse—A cow which drops her calf in the fall will give more milk from the same feed during the year, than will one that comes fresh in the spring. Of course, one must have warm stables, and other favorable conditions to do it. For myself, I have no patience with a man who allows his cows to go dry four months of the year, when milk is worth double the price it is in summer. But, one must have suitable foods, such as silage or roots, to balance his other foods. Dry hay, corn stalks and straw will not produce milk.

How many of you are doing winter dairying?

But few responded.

How long do your cows go dry?

Answer—From December or earlier, to April.

Does winter dairying pay here?

Yes, when we can market our milk; but most of our factories close in November.

Q—To Mr. Richardson—Do you advise the making of home-trade or export cheese?

Answer—I handle both export and home-trade cheese; but, my opinion is that we should consume more cheese than we now do. The trouble is, we eat too little, although but a small part of our cheese is exported; but that regulates the price for our home consumption. Then, a large amount of export cheese goes into cold storage when prices are lowest, which comes out and competes with that made later on, which keeps the price down. We can, as a rule, get as much for our home-trade cheese as for our export goods. Lewis county makes the best cheese in the state, and the state the best in the Union. Reports from the factories in this county show that more money is received per hundred pounds than in any other county in the state. I believe that the dairymen of the county should seek a larger, wider home market, then make just the quality of cheese that is called for.

Q—Is it worth $1 per hundred pounds to make our cheese?

Mr. Richardson—I do not believe that any good cheese maker can make it for less than a cent a pound. We need a man having a good level head, to make cheese, and to get him, we will have to pay him, just as we will have to pay any other good man for other good work. Lewis county cannot afford to employ cheap cheese makers.

Belleville, N. Y. C. W. JENNINGS.

Some Good Thoughts.

ED. HOARD'S DAIRYMAN:—Having been a subscriber and reader of HOARD'S DAIRYMAN for a number of years, my observation and experience has led me to appreciate the value of your paper to the farmer and stock raiser of to-day.

In this age of progress and civilization when everything is wending its way to the highest stage of perfection; when scientific principles are being applied to every pursuit in human life; when a man's success is in a direct ratio to his education; it is apparent that the first essential is knowledge. It is important "to know."

It would be little less than folly for me to assert that every farmer in order to be successful should be the possessor of a college education. Not at all. The means of the ordinary farmer would not allow it. But education is not alone found within college walls. Many of our successful men of to-day, as far as institutions of learning are concerned, never saw more than the ordinary high school. Some not that. Their success is mainly due to the periodicals, and their relations and associations with other men.

In my mind, Mr. Editor, money is wisely invested by the dairyman and farmer who would succeed, when placed in a subscription to a good periodical, devoted exclusively to a full and free discussion of all matters pertaining to his occupation, in this manner coming in contact with his fellows from all parts of the country. As I have previously stated I believe HOARD'S DAIRYMAN a valuable educator to the farmer and stock raiser of to-day.

Being born on a farm and having worked at farming in my early days, I have taken more than ordinary interest in the occupation. In the town of Deerfield, Oneida Co., N. Y., less than two miles from the city of Utica, I purchased some years ago what is known as "Fine View Farm." It has been my aim to run that farm according to the most modern methods.

In stocking my farm I put on grade Jerseys, which I believed to be good milk and butter cows. I purchased a thoroughbred Guernsey bull, Springdale, H. R., No. 1596, raised calves from the best cows and am milking them in my dairy at the present time. This cross has given me very satisfactory results. For the year ending April 30th, 1898, the cows averaged $56.00 per head in milk alone, some of the younger ones being fresh in October and November and were not in the dairy until the fall of that year. One of my grade Guernseys, "The Belle of Fine View," fresh in October, gave as high as 52 pounds of milk in one day; another, a grade Jersey, gave over 40 pounds of milk, the former making over $5.00 and the latter $4 00 per week. Neither of these cows had any feed other than what they picked in the field.

My milk is sold at wholesale and delivered every morning to a dealer in the city of Utica.

I have been quite a little interested in different articles appearing in your paper both pro and con the dual-purpose cow. While I do not wish to attack any statements made in support of dual-purpose, yet my experience has led me to oppose such a theory. Beef and milk are ends which should be striven for separately. I believe it is impossible to get good results together in the same animal. It would be ridiculous to assert that good drafting and racing qualities can be found in one and the same horse. The race horse is from a family of racers, while the draft horse is from another kind. Just so is a good milk and butter cow bred from a family of milkers, while the cow raised for beef is from another distinct family.

In this section of the country, the poultry business, if intelligently carried on, is a paying venture. In chickens, raised on an extensive scale, there is money. In connection with my dairy, I have this year added a poultry department to my farm. The erection of a brooder for the accommodation of 2,000 chickens and ducks has just been completed and the same fitted up according to the latest improved plans. About the first of December, the imcubators are started and the poultry raised during the winter months, so that eggs and broilers can be put on the market during March and April. My poultry is all full-blooded and I intend to raise nothing but the best.

An Old Proverb That—

but just as forceful today as one hundred years ago.

It's good common sense advice in almost every transaction, but for present purposes let us suppose you are going to buy a binder, a mower or a corn harvester.

Possibly you have made up your mind to get something cheaper than the **Deering Ideal.**

Perhaps it is not yet too late to "go back." And it certainly *is* "better to go back than to go wrong."

That word "cheaper" is an old fraud. Do not be deceived by it.

Deering Ideal grain and grass harvesters are "ideal" because they embody the best thoughts and suggestions of the farmer and the mechanic.

They are simple, scientific and substantial.

They are the cheapest to buy because they are the best to own.

DEERING HARVESTER CO., - Chicago.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade was unusually light, only 1500 pounds being placed on sale. This sold at once at 16⅜ cents. The Quotation Committee announces the market firm at 16 cents. The sale made was:

Factory.	*Pounds.*	*Price.*
Red Clover.....	1500	16⅜

The markets for the corresponding week of the three preceding years were as follows:

May 9, '98, no sales, market price, 16 cents.
May 10, '97, 35,230 pounds of butter sold at 14½c.
May 11, '96, 46,930 pounds of butter sold at 15½@16c.

The New York market was reported steady at 17 cents. H. C. B.

Elgin, Ill., May 8, '99.

Studying the Cow Machine.

ED. HOARD'S DAIRYMAN:—During the summer of 1898, the Kansas Experiment Station started an investigation among the creamery patrons of the Meriden Creamery Co., in order to find out what the Kansas dairy cow was producing, and to compare these results with those obtained by the College scrub herd. This would enable the station to offer suggestions for improvement.

Realizing the benefit to be derived from keeping in touch with the patrons, the Meriden Creamery Company has recently written for a list of the questions used by the Experiment Station, last summer, with the remark that the company intends to have their skimming station men visit each patron some time in the next few months. Having three of the graduates of the Kansas Dairy School in its employ, this company will be able, not only to make this investigation, but at the same time to offer suggestions to the patrons along the line of feed and care of the dairy cow, and the handling of milk. The practices of the most successful patrons can be used as object lessons for those less successful. In this way the creamery becomes an educational center, where valuable information is received and dispersed.

The effort is certainly a commendable one, and should be followed by other creameries. Find out what the cows in your neighborhood are doing, compare them with the standard of what they should do, and then work to improve them. No dairy should be content to keep a cow that gives less than 5,000 pounds of milk per annum, and should not rest satisfied until his best cows yield annually between 8,000 and 10,000 pounds of milk.

The record of the college scrub herd, with cows below the average of Kansas, shows that this can be done. If dairying is to be made more profitable, more attention must be given to studying the cow machine with a view of increasing her efficiency. Any effort put forward along this line will result in profit, both to the creamery and to the creamery patron. Now is the time to act.

D. H. OTIS.

Kansas Experiment Station.

A Word of Caution to New Creamery Associations.

[Press Bulletin.]

The writer has received a number of inquiries of late in regard to the methods employed by "creamery promoters" in establishing creameries. From the reputation that these "promoters" in general bear, it would seem wise to give them a wide berth. It is their business to build and equip a creamery and get their money for it, regardless of the subsequent success of the enterprise. To do this, they misrepresent the amount of milk that can be expected from a given number of cows and the average price that can be obtained for the butter, and they usually charge much more for erecting and equipping the plant than it would cost the Creamery Association, if purchased at market rates.

By misrepresenting the profits to be derived from the creamery business, "creamery promoters" have induced thousands of farmers to pay for expensive creamery plants which are now standing idle and not only yield nothing on the investment but are constantly deteriorating in value.

In order for a creamery association to be successful, it is necessary, above all things, to have the milk from 300 to 500 cows guaranteed to the creamery for nine or ten months in the year. A creamery to handle this amount of milk can be built and equipped from $1800 to $2,200. The price usually asked by "promoters" is from $2700 to $4000.

If it is desired to build a creamery in a community, an informal meeting of those interested should be called. Then, if a sufficient number of cows can be guaranteed, an effort should be made to get the manager of a successful creamery to come and thoroughly explain the advantages and disadvantages of a creamery and give his suggestions as to building and equipping a plant.

A committee should likewise be appointed to visit one or more well managed creameries. "The creamery promoter" should be kept away from these meetings.

By appointing suitable committees to carry out the plans adopted by the stockholders, a creamery can be built and equipped at a comparatively small cost and its success be assured from the start. A very useful and suggestive bulletin entitled "Creameries and Butter Factories" has recently been issued by the Dairy Division of the U. S. Department of Agriculture at Washington, D. C., and may be had for the asking.

Pa. Exp. Station. H. HAYWARD.

Manuring Soils Naturally Rich.

It may seem absurb to talk of manuring soils naturally rich, yet the evidence of our official statistics tends to prove these naturally rich soils have a very low productive power. The low average yields per acre of wheat and corn on our rich prairie soils is often quoted as a kind of national reproach. There seems to be no doubt of the fact that these soils are rich; there is certainly no denying that they give a very low acre yield.

Low acre yields on rich soils is practically invariably due to inequalities in the supply of fertilizers or manures. A soil rich in organic matter is likely to be rich in fertilizer nitrogen, but may be relatively deficient in in fertilizer potash and phosphoric acid. In a natural state the potash and phosphates have been used over and over again in making crops of grasses, more or less of which belong to the legume family. Thus, there has been a constant increase in the supply of fertilizer nitrogen, but no corresponding increase in the supply of potash and phosphate. The result is that the soil becomes charged with vegetable matter moderately rich in nitrogen, but low in the mineral fertilizers.

Under these conditions, fair crops of stalks of straw may result, but the grain will be low in quantity. Potash and phosphate are the determining fertilizer ingredients in producing the seeds of plants; if there is present in the soil relatively more available nitrogen than available potash and phosphate to properly accompany same, the yield of grain (seed) is controlled by the deficient mineral fertilizer. The strength of the chain is the strength of its weakest link. Even the yield of straw and stalks cannot go beyond a certain limit with a deficient supply of potash and phosphate, though the nitrogen be abundant.

Though such soils are called rich, they are rich chiefly as regards nitrogen only, and too much nitrogen is only a trifle less harmful than too little, especially in grain farming. These rich soils will amply repay manuring with mineral fertilizers. They do not require heavy manuring, or fertilizing rather, as do the more exhausted soils of the Atlantic coast line, but the small quantity needed is just as important as the larger applications found necessary in the east. One hundred pounds of acid phosphate and 50 pounds of muriate of potash per acre will make a great showing, though doubtless twice as much would still show a handsome margin of profit.

Any form of chemical fertilizer supplying potash and phosphoric acid may be used. Finely ground bone meal is very useful as a source of supply of the latter, while muriate of potash would be cheaper per actual pound of potash than kainit, on account of the high freight rate. The combination would show up well. S. COX.

The Woman's Side of Creamery Work.

Patronizing Creameries.

The following is an extract from a letter, written by Mrs. Jeanette Wragg Miller to the *Wisconsin Farmer*, in which she advises farmers to send their milk to the creameries:

"Now if the milk is sent to a creamery, all the wife has to do is to wash and scald the cans with soda water and set them in an airy place until needed. Whoever does the milking will strain the milk and the hauler will come to the door and get it and bring back the separated milk. It makes no work for the wife, and she will have the two or three morning hours that are usually spent in dairy work, to employ in other occupations, or, if the weather is fine, she will enjoy going about with her husband at his morning chores, and with him admire the stock and poultry. The husband will enjoy this as much as the wife.

I have heard some men say that separated milk was not fit for calves and pigs. I know better than this, for while it may not contain as much nutriment as home skimmed milk, it is still good if fed with judgment. We have marketed pigs at seven months old that weighed 200 pounds, and they had been fed on creamery skimmed milk, with grain of course. We have also raised calves on it that looked as well as any that run with the cow. Some may laugh and say it is impossible, but I'll tell you how we do it, and I generally do this part of the work myself. I put a handful of oil meal and a large handful of corn meal in each pail and pour about three pints of boiling water into it, let it stand a few minutes and then put in milk enough to make it just milk warm. My husband feeds them and the work ought never to be trusted to children. We are now feeding three calves and they look well. Each one eats shelled corn, oats and hay before it is one month old. We always give them new milk for ten days or two weeks

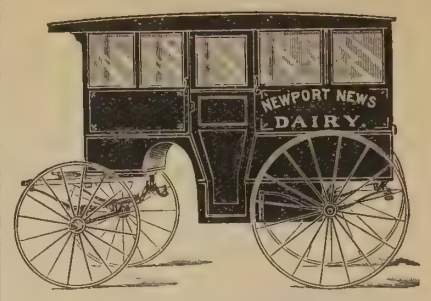
"BURNING MONEY."

The most precious possession on earth is perfect health. It is the ground-work of all prosperity in life; and few people grudge any reasonable expenditure which will be the means of restoring it; but one of the most disheartening things in the world is for any one who works hard for his money to keep paying it out for doctors and medicines that do no earthly good. It is like throwing it into the fire.

"We had spent lots of money for doctor bills and I had almost given up in despair," says Mrs. Ella Schall, of Moosehead, Luzerne Co., Pa., in a sincere letter to Dr. R. V. Pierce, of Buffalo, N. Y. "Then I told my husband I was going to write to you. I am very glad I did so; You remember my case was abscess of the breast. Dr. Pierce's Golden Medical Discovery cured me in one month, sound and well."

"Your kindness to me I can never forget," writes Mrs. Josie E. Clark, of Enterprise, Shelby Co., Mo. "I cannot express half my feelings of gratefulness to you. I had despaired of ever getting well. I had been in bad health for twelve years. Had aches all through me, numb hands, cold feet, and everything I ate distressed me; my bowels were constipated. I was very nervous, depressed and despondent. When I first wrote to you I thought I could never be cured. I have taken six bottles of Dr. Pierce's Golden Medical Discovery, and my health is now good. You have my honest recommendation to all sufferers. I think there is no medicine in the world as good as Dr. Pierce's."

It's an insult to your intelligence for a dealer to attempt to palm off upon you a *substitute* for this world-famed medicine. You *know* what you want. It's his business to *meet that want*. When he urges some *substitute* he's thinking of the larger profit he'll make—not of your welfare. Shun all such dishonest dealers.



Every sick person in this land should possess Dr. Pierce's grand thousand-page illustrated Common Sense Medical Adviser, which will be sent free for the bare cost of mailing, 21 one-cent stamps.

and gradually change. You will doubtless say that this is lots of work. To be sure, but what is gained in this world without work, and it is through these small gains on the farm that the farmer makes his money.

Having always kept a strict book account, from the buying a postage stamp to the selling of a horse, I can give you some exact figures of what we made on a few cows besides raising their calves. From October 1, 1893, to June, 1894, from five cows running in pasture with hay at night and without extra feed, I sold butter (besides what was used in the family of four and such company as came, and we used no small quantity) to the amount of $98.72. For some of this I got 22 cents a pound, and I only sold ten pounds of it for less than 20 cents. The next year we sent the milk to the creamery, and for the same time, from October 1, 1894 to June 1, 1895, from the same cows on the same kind of feed, after the hauling was paid for and we got our own butter and cream, we received $118.28. Don't imagine that I think this any butter record. Our cattle are not special butter cows. We raise cattle more for beef, yet we mean to make all we can out of the milk. If the cows had been fed on ground feed they would, of course, have done better, but I give these figures merely to show the gain in patronizing a creamery over making butter.

If a wife's strength coun's for anything, I think the gain on this account trebles that of dollars and cents, and in these progressive times a woman's time can be better employed than working in the kitchen three-fourths of the time. Let machinery do all that it will to save her and give the farmer's wife more time to get out into the world."

CONCERNING OUR ADVERTISERS.

Every line of manufacture has been advanced by the use of modern machinery. But a few years since the buggies, the carriages and the harness of all of our farmers were made in country shops by skilled workmen. They cost quite a lot of money too. It took many a hard month's work of the farmer boy to pay for a buggy. But the designer and the machinery inventor have done a great deal to lighten the load on his pocket, and to day he can buy a better built and far handsomer buggy for twenty six to thirty dollars than he could get for a hundred ten years ago. It is machine made, which means that it is well made. It is more graceful in outline, more stylish looking and is a lighter load on the horse. It rides more easily, and it will last longer than its predecessor. One of the most successful houses in America, handling these buggies is the Crawfordsville Carriage and Harness Co., of Crawfordsville, Ind. The man who buys from it has no middleman's profits to pay. He gets the worth of his money. The company issues a handsome catalogue which can be had upon application.

A gentleman who has received one of the handsome new catalogues from Hood Farm, Lowell, Mass., writes as follows, "Mr. Hood deserves the thanks of the Jersey World for preserving in such beautiful form the portraits of his splendid herd which I believe to be unexcelled in this country. The catalogue is a work of art as well as a work of love for one of the most lovable of the animal creation."

MORE WORK WITH LESS HELP.

How to do the greatest amount of work with the fewest men and horses is a most important problem for farmers. The efforts of many inventors have been directed to the solving of this problem. Hundreds of machines and implements have been devised to take the place of human labor in farm work. The most successful implement that has been introduced in recent years, if we accept the testimony of its users, is Hallock's Success Anti-Clog Weeder and Cultivator. Mr. L. B. Marsh, of Trempealeau, Wis., writes of this implement af follows;

"I tended last season 75 acres of corn and potatoes with the Success Anti-Clog Weeder, and I am in my 70th year. I must say I never before saw such clean fields of corn and potatoes in my life With the weeder I did with one team as much work as three men and three teams could do with the old style cultivators, and did the work in a very much better manner, too."

D. Y. Hallock & Sons, York, Pa., the manufacturers of the Success Weeder, will be glad to mail sheets of testimonials and full information to any one who requests them.

PROSPERITY.

Greater Prosperity among the farmers is the mission of the McCormick. Speed at harvest time is all important. Prompt saving of crops means money in the farmer's pocket. Delay means loss, speed means profit. Buy the Mc Cormick and you will get your full money's worth. Mc Cormick sets the standard in Binders, Mowers, Reapers, Corn Harvesters, Rakes and Shredders.

CATALOGUES BY CARLOADS.

A statistical genius has figured that the various manufacturers of harvesting machinery have printed and distributed enough "advertising matter" during the last decade to fill 2,000 freight cars. The greater portion of this literature has been expended on the farmers of this country in an effort to make them believe that almost any kind of a machine is "as good as the Deering." In the meantime the Deering Harvester Company of Chicago, has prospered, until at the present time its works employ more hands than any single manufacturing plant of any kind in America.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

SORE TEATS.

Will you give me a remedy for our cows; teats are very sore; at first little white blisters appear, which soon turn to large sores, and in some cases part of the udder swells and cow gives lumpy milk from that part. In other cases cow will be all right when turned out, without any sores at all, and will come up with one quarter of udder swollen and fevered, and milk will be lumpy, as in other cases. All cases of sore teats do not develope into swollen udders with lumpy milk. Cows were given cotton seed hulls, meal, and wheat bran during winter. Spring has opened now, so will not feed any more hulls. Would hulls cause the above disease?

TOWER HILL DAIRY.

Kingston, N. C.

ANSWER.

Cow pox. Immediate full dose of physic and repeat, one or two times if needed. Rub swelled udder with strong camphorated spirits six parts, common turpentine two parts only. Rub hard twice first day, then as needed. Dress sores with spermaceti and almond oil, equal parts, and one dram to one ounce of gum myrrh, to be intimately mixed.

Hulls cause many queer and puzzling ailments. Don't forget the physic.

TUMOR ON KNEE.

I have a cow with large bunch on her knee, as large as a tea saucer. It came there this winter. I think it came from lying down against the stanchion. The bunch is quite soft and feels like there is water in it. I run a knife in it, but only a little blood run out. It does not lame her.

Wyoming, Wis. W. C.

ANSWER.

Lancing was a serious wrong, indeed. Paint it over twice a day with strong tincture of iodine. This will need to be done systematically for quite a long time, or it will do little good. Must be done at the same time each day. Keep off the knife.

LUMP IN BAG.

I have a fine Jersey heifer ten months old. Noticed her bag was growing considerably. Upon examination found a round, hard lump, apparently in the right side of her bag. It seems about two and one-half inches through, but not much sore. Is it possible that it might injure her future usefulness as a cow? A SUBSCRIBER.

Cluster, W. Va.

ANSWER.

I should judge some injury the cause. No, it does not follow that such should destroy the usefulness of the cow. Still, it is possible. Such is a blind tumor. Paint over the spot, only, with strong tincture of iodine three times a day for a while. Internally give forty to fifty grains of iodide of potassa in a little cold water, each dose as a small drench, for ten to thirty days. Give good out door exercise daily.

MILK NOT COME.

Have a heifer dropped a calf two weeks ago. Her udder is not broke yet; am rubbing it thoroughly, twice a day with olive oil and tincture of opium. Can I use anything else that will bring into right condition soon? I do not seem to make much if any headway with the remedy now in use.

W. E. B.

ANSWER

You are simply feeding the already bad condition. Physic, physic, two to three times, five days apart. Rub udder hard with strong tincture of camphor, six parts, common turpentine two parts, only. Use much hand massage, rubbing, kneading and squeezing, gently, daily. Keep away the oil. Milk her dry three times a day. Give good exercise by driving her, and so direct the blood to the general circulation. Physic is your grand remedy, so do it faithfully and well.

SUDDEN DEATH OF COW.

I lost a cow so strangely, and so far removed from all my experience, that I lay it before the readers of the DAIRYMAN to see it anyone can clear up the mystery.

The cow was a medium size Jersey, in fine condition all winter. In April an eruption appeared on her skin. I not being acquainted with it, consulted the local veterinarian, who gave me a wash to put on, and dry it up, pronouncing it entirely local, and not anything serious. It was slowly doing the work. When the veterinarian asked how she was getting along, I said slowly. He replied, give a good drench of one pound of salts and one-half pound common salt. He sent it up, and after supper gave it to the cow. In thirty minutes she was dead. She seemed like one affected with the heart disease. She was eating heartily, and was in fine flow of milk, and the purgative is our common remedy for ordinary cases. I believe it is general.

Norfolk, Va. I. C. W.

ANSWER.

The physic was all right. The half a pound of salt was far from good practice, and did the final mischief. There is nothing at all of a mysterious nature in the skin disease named. She had some form of itch, scabies or mange. These forms are familiar, and are quite common to both cows and horses, usually the result of neglect in sanitary measures.

SWELLED NECK.

I have a cow that had swelled neck and chops, could not eat nor drink for a day or two, but I poulticed it and it is better now but don't seem to get over it, breathes hard and coughs as though there might be something in her throat, like phlegm or a discharge, sticks her nose straight out. A. S.

Hinesberg, Vt.

ANSWER.

The best advice I can give you, is to have an expert make an internal and external examination. I don't think it tuberculosis. I don't believe it is contagious. There may be some obstruction by lodgment of food, etc.; an examination alone can determine this, and must be a practical man to make the examination.

CAUSE OF MANGE.

Will you please inform me what causes the mange on a horse, and what is the remedy? W. D K.

Philadelphia, N. Y.

ANSWER.

Neglect, poverty and filth is the father, mother, and grandparents of mange. As a rule, good, nutritious food in plenty, and work in moderation. Wash with strong tar soap some warm day, in the sun. Rub in well. Use the curry comb and brush thoroughly each day, and keep them from the unaffected, or they will be likely to be infected. Rub dry after each washing.

BLINDNESS IN CALF.

I have a very fine calf, now one month old, which was born blind. Kindly suggest a mode of procuring vision for it. Its mother was fed liberally on cotton seed meal. a few weeks previous to delivery. I. H. D.

Hamilton, Ga.

ANSWER.

You don't give the condition of the eyes, so I can't even form a proximate professional opinion as to the ailment. But I am quite sure no remedy of mine would avail in such a case. A personal, close and careful examination might suggest the true condition. I look upon all such cases as hopeless, unless the blindness is caused by a film or skin over the eyes.

SORE UDDER.

I have a cow whose bag spoiled last fall, soon after calving. I tried everything I could find recommended, all of no avail. One teat is dry and I'd like to dry her off, but she still gives a white mattery substance from the three teats; the bag has burst in four or five places and doesn't seem to get any better. I haven't milked her regularly for two months. W. S. H.

Mattoon, Ill.

ANSWER.

Dress the sores with the compound myrrh and aloes twice a day. Give her one or two doses of physic, 5 days apart. As soon as the sores are healed, fatten her. She will not be at all likely to ever be fit for a milk cow.

SWOLLEN UDDER.

I have a cow, the skin of her udder is swollen and hard; the swelling extends about one foot in front of udder, and in two places there is a scab on udder. The cow has had sore teats about two months. Cow appears in good health. When she is milked the skin hangs loose. W. J. T.

Stillwater, Minn.

ANSWER.

Immediate full dose of physic, and repeat two or three times if needed, five days apart. Stop at once hand milking, or you can't cure the sores. Select the easiest and best milk tube. See ads. in DAIRYMAN. The same camphorated liniment daily, for a while, as above.

Horse Owners! Use

GOMBAULT'S

Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.* Every bottle sold is warranted to give satisfaction Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars.

ABORTION!

Retention of Placenta and Failure to Breed.

H. W. KELLOGG'S experience with and positive cure for these diseases in cows. Send for circulars. Address all communications to

H. W. KELLOGG COMPANY, Ripon, Wis

It Also Cures Calf Cholera.

STORM LAKE, IOWA, March 22, '99.

H. W. KELLOGG, Esq., Ripon Wis.

Dear Sir:—Have now made use of your condition powders twice in my herd and am highly pleased with the result.

I heartily recommend the powders to others and will say that I am better pleased with their use than that of any other remedy for "Abortion," "Failure to Breed," and "Calf Cholera." During the past year I have had much trouble and loss from Calf Cholera and found no relief until I commenced feeding the powders to my cows, when the trouble soon passed away and now the calves are coming along in fine shape.

Very respectfully,

GEO. H. EASTMAN.

ANTIABORSIO.

WILL PREVENT ABORTION in cows and cure scours in calves. One gallon will treat twenty cows three months.

Our Specific No. 1: Absolutely prevents Hog Cholera and Swine Plague, and will cure 90 per cent. of sick hogs

Our Specific No. 2: Prevents and cures Roup and Gapes, and kills Vermin on Poultry, also kills **Ticks on Sheep.** These are established facts, not experiments.

Our remedies are liquid germicides applied by sprinkling in closed stables and pens. Cures by inhaling fumes which destroy the germs of disease.

Send for free booklet and testimonials.

Animal Germicide Co., 319 Washington St., N. Y.

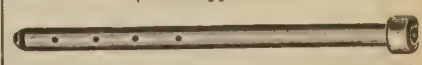
Wilbur Seed Meal Company,

185 2nd Street, - MILWAUKEE, WIS.

Dr. Horne's Anti-Abortient

Prevents Abortion and cures Nymphomania—failure to breed; also Emmenagogue Powders for cows failing to come in heat. Both powders are the result of long practical experience and study and may be given in a little moist feed. 5 oz. $1, 11 oz. $2, 23 oz. $4, 50 oz. $8, by mail.



Also Specific for

SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM. HORNE, Janesville, Wis.

New York Farm and Dairy Notes.

An Early Spring.—Progress of Farm Work.

ED. HOARD'S DAIRYMAN:—The spring is usually early in south-east New York. At this time, May 1st, the trees are nearly leaved out, and the grass has made considerable growth. The weather has been very favorable to the farmers thus far. The ground has been in good condition for sowing grain, for two weeks. The oats are nearly all sown, some potatoes have been planted, and some farmers have prepared the ground for corn.

The plan of farming that has been so long practiced in this vicinity, I think, is somewhat changed. The old plan was to grow sufficient grain to feed the teams, grow potatoes for family use, plant a small field of corn, which was husked by hand, ground and fed to the hogs. A small field of fodder-corn was grown, but the corn was sown thickly, and the quality of the fodder was very poor. Very little grain was fed the cows, and that was fed early in the spring before grass.

One can see that the methods of farming are being changed to meet the new conditions in dairy farming, although in some localities the progress is slow. One can see that many farmers are working in the direction of cheaper feed for the cows. In planting their farm crops, they are planning to grow something to feed the cows that will save a part of the grain bill. They begin to see that the way of success is in the direction of carrying the maximum number of cows on the farm, and making the farm feed the cows.

Working along this line, many farmers are realizing that it is more economical to provide soiling crops for the late summer and fall, and ensilage for the winter, than to buy grain to produce the milk, which is now demanded of the dairyman in the winter. From my observation, I know that more farmers have sown oats and peas this spring for the early soiling crop, and that a large acreage will be planted to corn for ensilage.

PLANTING THE ENSILAGE CORN.

On our farm the plan has been to plant the corn on ground that has grown a crop of clover. During the winter the manure had been drawn directly from the stable, and spread on the clover sod. The ground was plowed in the spring, and prepared for planting the corn.

The corn is planted with a horse corn planter, and a little fertilizer drilled in with the corn. The Mastodon variety has proved the best for ensilage in my locality. It makes a large growth of stalks, and if planted early will mature ears sufficiently to make good ensilage. We can plant several acres in a day, and its cultivation is made much easier with the modern tools.

The cultivation with the weeder should begin soon after planting, and kept up until the corn is two or three inches high. Two or three crops of weeds being thus destroyed, the subsequent cultivation will be much easier. It pays to cultivate the corn frequently, but the cultivation should be more shallow as the corn grows larger, and the roots extend across the rows. We have planted the corn in rows three feet apart, and set the planter so it will drop the kernels about six inches apart. We get a large bulk of stalks, and nearly all grow ears of corn. We think when we cut the corn when the ears are in the milk stage of growth, we have the best ensilage that can be produced.

Many make the mistake of deferring the planting until late in the season, then planting the large growing varieties that will not mature before frost. The late plantings should be made with an earlier and smaller variety of corn.

A CREAM SEPARATOR FOR A SMALL DAIRY.

I have a neighbor who bought a cream separator for a dairy of 15 cows, and he tells me that the extra butter he has made by using it, has paid for the separator in one year. It seems to be the concensus of opinion of all the people who are using separators in the small dairies, as far as I know, that they are profitable. Good authorities have stated that one per cent of butter fat is saved with the separator. This means that twenty to twenty-five per cent more butter can be made.

A dairy of ten fair cows should make 2,000 pounds of butter. If twenty per cent more could be made with a separator, it would amount to 400 pounds of butter, which nearly pays for the separator in one year. This is surely a good investment, and would be if only one-half the amount named is saved with the separator. A good separator will last many years, with only a small cost for repairs. There is also a considerable saving of labor, as the house for the separator can be near the stable, and the milk carried to it and run through the separator, and the milk can be fed at once to the calves while it is warm.

I well remember the hard work of carrying all the milk to the dairy house several rods distant, and in cold weather warming the skim milk and carrying it to the calves. The cheapest power for most small farmers, with which to drive the separator, is a tread power on which a bull can be used. Such a power can be purchased for $50 or less, and the bull is the better for the exercise.

I know people who keep only five cows, and use the small hand separators, and they are much pleased with them. W. J.

Delaware Co., N. Y.

A GOOD DAIRY.

N. I. Swezey, of Andover, Ohio, who farms it on a small scale on about 1,000 acres, was telling us that on one of his farms, where he has over forty cows, they averaged 5,000 pounds of milk last year, and in connection with it, he said that a visitor at the farm, one day at milking time, remarked that the cows all gave a pailful. "Yes," the tenant said, "if they do not Mr. Swezey trades them off for a cow that does," and therein lies the secret of the money in milk. It costs no more to keep a good milker than a poor one. How many farmers through the country know what each cow in their dairy is doing?—Jefferson, Ohio, *Sentinel*.

Even the editor of the *Sentinel* seems to understand the true principle of profit making in the keeping of cows, and yet, no doubt, many of his readers, who are contented to keep poor cows will say, "Newspaper men are so theoretical!" "What can they know about practical dairying?" Suppose the editor should point to their practice, of keeping a cow at a loss and taking no pains to know it, and ask if they called that practical.

Write Macbeth Pittsburgh Pa

Rupture Book Free.

HOME METHOD THAT RESTORES NO MATTER HOW BAD THE CASE.

Welcome Advice From A Well Known New York Specialist.

A prominent specialist in the cure of rupture has written a book on the subject and tells how any sufferer can cure himself at home at slight expense. And the best of it is that he has published this book for free distribution. Printing

MR. F. L. WILLEY.

is, nowadays, such a rapid art that it doesn't cost a great deal to get out a neat book and give it away. The book is written by Dr. W. S. Rice, 353 W. Main St., Adams, N. Y., and by merely sending your name and address he will mail you a copy free of all cost. The portrait above is that of Mr. F. L. Willey, Shelton, Wash., who was cured of rupture by Dr. Rice. Mr. Willey says:—"I sent to Dr. Rice for one of his books on rupture and found it very valuable. The information therein was the first real knowledge I had ever received that could convince me that rupture was a curable malady. I used his home treatment and am glad to say that my rupture was perfectly cured and that I haven't had any return or noticed any difference between the healed place and any other solid part of me. I was cured sound and well."

Readers are requested to write at once for this free book. No matter if you are wearing some kind of a truss that affords some relief send at once and learn all about the new home cure which Dr. Rice has clearly explained and fully illustrated. Write today and if you know others who are ruptured ask them to write. It contains advice that may save your life.

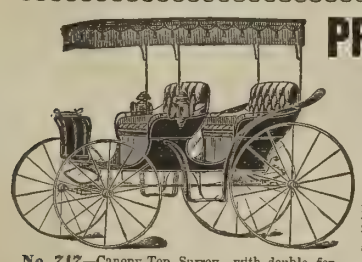
A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

We make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.



THE ONLY LOW-DOWN

Short Turn, Straight Bottom, Short Coupled, Light Draft Wagon on the Market.

20 INCHES FROM GROUND to bottom of body. Will turn as short as any cut under reach wagon. Strong construction, nicely finished. Send for Catalogue, prices and terms. Wagons for carrying bottled milk a specialty.

It's close enough and strong enough to turn all live stock. Keeps yours in and your neighbor's out. We want good agents in every locality. First order secures township agency. Circulars free.

Pittsburg Woven Wire Fence Co., 17 Penn. Av., Pittsburg, Pa.

THE NEW BOOK Feeds and Feeding

By Prof. W. A. HENRY.

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premum.	or	Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

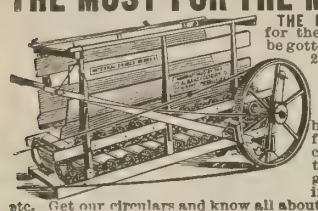
Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

COLOR and flavor of fruits, size, quality and appearance of vegetables, weight and plumpness of grain, are all produced by Potash.



Potash,

properly combined with Phosphoric Acid and Nitrogen, and liberally applied, will improve every soil and increase yield and quality of any crop.

Write and get **Free** our pamphlets, which tell how to buy and use fertilizers with greatest economy and profit.

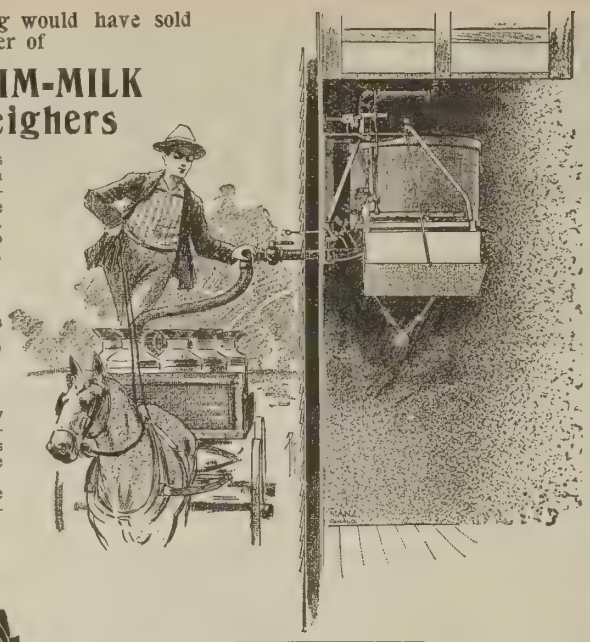
Do You Know What a Good Tester Is?

It is one that makes little noise; that has small vibration; that runs easily; that will do accurate work.

THE STANDARD BABCOCK TESTER

will last for years. It is built for the creameryman who believes that it pays to have **high grade machinery at a reasonable price.** The Standard Tester has a solid cast iron frame and is supplied with the famous Glass Eye Speed Indicator.



IT USES THE ORDINARY BABCOCK BOTTLE.

Farrington and Woll's new book on Milk Testing with each machine. We are prepared to repair all separators, and have the most experienced men for this work. You will be interested in our free catalogue No. 61.

Address, ELGIN MANUFACTURING CO., ELGIN, ILL.

No amount of Advertising would have sold the number of

IDEAL SKIM-MILK Weighers

Which we have placed this season if it had not been a good machine. It is acknowledged to be the best machine on the market for the purpose. It costs more than a milk pump and some so-called weighers. But it does the business.

It will distribute a run of 30,000 or 40,000 Pounds and only have 25 to 50 Pounds Left.

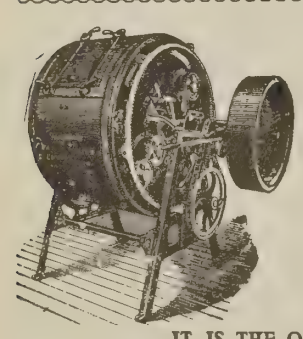
It does what we claim. We fully guarantee it. We ship it anywhere on trial. If after 30 days in actual use it does not prove satisfactory, we take it back Our Weigher received the Gold Medal at the Omaha Exposition.

. . . A . . . SANITARY Milk and Cream Ticket.

A coupon milk and cream ticket is the only milk or cream ticket that complies with all sanitary requirements, and is also the only milk ticket by which a complete check can be kept on both customer and driver. We would like to send you a sample.

We have a large up-to-date and complete line of Milk Dealers' Supplies. Everything you need. Our Ideal Milk Jars and Caps are the best on the market. Write for sample.

Our latest Milk Dealers' Price Current contains new ideas and new apparatus. May we send you one?



Alpha De Laval Separators, Ideal Skim Milk Weighers, Elgin Style Ash Tubs, Spruce Australian Butter Boxes, Ideal Turbine Testers, Stearns' Style Spruce Tubs, Ideal Corrosive Sublimate Tablets, Refrigerating Machinery, Ideal Cleansing Powder, Etc., Etc.

Creamery Package Mfg. Co.,

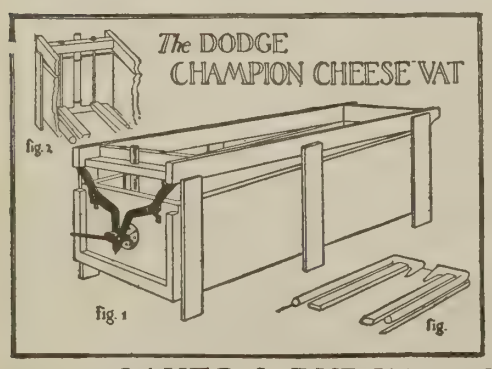
THE DAIRY "VICTOR" Churn.

This Combined Churn and Butter Worker is proving itself to be precisely what the farmers and dairymen have been seeking after. It's work is as complete as the work of the "Factory" Victor Churn, which is rapidly supplanting every other Combined Churn and Butter Worker.



IT IS THE ONLY SUCCESSFUL DAIRY COMBINED CHURN AND BUTTER WORKER ON THE MARKET.

It is easy to handle, easy to clean, perfect in its work, durable and reliable. It charm every farmer and dairyman who sees it work. Manufactured by . . .

F. B. FARGO & CO., Lake Mills, Wis.

THE DODGE TILTER

....FOR CHEESE VATS....

An important improvement Tilts vat tin only, thereby avoiding racking the wood vat when drawing off the whey. Vat tin so supported that no possible injury can come to it. Requires but slight effort to throw the lever. Can be adjusted to any style of vat....

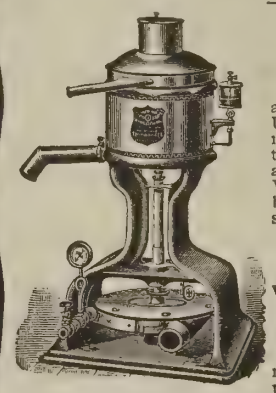
WRITE FOR PRICES.

OAKES & BURGER, CATTARAUGUS, N. Y.

ANY OLD STRIP OF TIN . .

With two nails will fasten the cover. Butter makers who care for the appearance of the package use the VICTOR. Strong and smooth. No tacks or sharp corners to injure the hands. C. E. Smith & Co., Westboro, Mass.

THE IMPROVED



U. S. Triple Current Separator

PROVES ITS SUPERIORITY EVERYWHERE.

AT THE STATE EXPERIMENT STATIONS.

Read a Few 1899 Reports.

Massachusetts, average of 19 tests, January 7th to 31st,			.033 of 1%
Ohio,	" " 19 "	" 10th to 21st,	.034 of 1%
Vermont,	" " 18 "	" 9th to Feb. 3d,	.038 of 1%
Wisconsin,	" " 17 "	" 2d to 19th	.03 of 1%
An average from 73 tests of skim milk of			.034 of 1%

IN THE FACTORY.

The U. S. Takes the Cake.

POYNETTE, WIS., Jan. 20th, 1899.

Have been running U. S. Separators since 1892, and can cheerfully say that the new No. 1 Improved U. S. Separator takes the cake. When the skim milk is tested it shows only a trace of fat. I won the sweepstakes and three other first prizes, amounting in value altogether to $115.00, at the 1898 Wisconsin State Dairymen's Association, and all because my No. 1 U. S. Separator makes such smooth, perfect cream.

R. M. BUSSARD, Prop. Bussard's Creamery.

AND IN THE DAIRY.

Very Durable, Very Easy to Operate, Never Out of Order.

TIFFIN, OHIO, Nov. 28th, 1898.

Have used the No. 5 Improved U. S. Separator nearly three years and do not think it is worn a particle. It runs as smooth as the day we first started it. **It is the best separator in the world,** it is so easily run and so easy to clean, and it is always in order to do the best of work. We wonder how we ever got along without one. We think very much of the enclosed gearing. You have the best machine I know of in running and mechanical construction.

GEORGE D. SCOTT.

Subscriptions in United States and Canada $1.00 per year; 6 months 50 cents; 3 months 25 cents.

Foreign Subscriptions may be sent through Sampson Low, Marston & Co., St. Dunstan's House, Fetter Lane, London, Eng., or their agents, including the leading news dealers and book sellers in nearly all foreign countries.

All countries in the Postal Union $2.04 a year; not in the Postal Union $2.56.

Correspondents must not expect us to acknowledge the receipt of letters containing remittances for subscriptions. The receipt of the Dairyman is sufficient notification that the money has been received. The label on the paper will show date to which subscription is paid. In case of renewals if date on label is not changed within two weeks after remittance is sent, inform us at once.

Remit by draft on Chicago or New York, or Post Office or Express Order; never by personal check.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

In the Dairyman of April 7th was an editorial article on "The Effect of the First Impregnation on Future Progeny." The *Ranch and Range* of Seattle, Wash., reprints the article in such a way as to give the reader the idea that it is very largely original with that paper, and then has the ignorance to put over the same a caption entitled, "Impotence of the Sire," when it is anything but impotence that the article treats of. The *Ranch and Range* will find it safer hereafter, in printing extracts that it does not understand, to leave them as they appeared in the original journal, and give the proper credit.

The Indiana Experiment Station has issued a second bulletin on the use of skim milk as a food for growing chickens. The late experiments upon which this bulletin is founded, confirm the result of the previous experiment and show that skim milk is a valuable food for chickens. Its influence is great in securing increased weight and in maintaining the health of the fowls. The addition of skim milk to the ration increases the profits by decreasing the cost of the ration and enabling the fowls to more thoroughly utilize the other foods given them.

The Stave Silo.

After making for three years careful study and observation of the stave silo we believe it is the most practical and successful silo which can be constructed. The round stave silo presents no corners which may pull apart and admit air, and which cause the silage to settle unequally; the original cost is very slight as no expert labor is required; all mason and carpenter work can be done by the usual farm help. The material used in construction is the minimum amount for obtaining the maximum capacity. The durability of the stave silo is as yet only a matter of conjecture, for decay has not commenced on any stave silo which we have examined.

CONSTRUCTION OF FOUNDATION FOR STAVE SILO.

Where the silo is to be constructed an excavation should be made to a depth of 3 or 4 inches or to the bottom of the loose surface soil and with a diameter at least two feet greater than the proposed diameter of the silo and drainage should be provided if the conditions seem to warrant. The excavation should be filled with stones, large ones being placed at the bottom and smaller ones being worked in and pounded down toward the top. Gravel, if well pounded down may serve as filling between the stones. It is important that the pounding be thoroughly done, otherwise settling will take place later on and the cement finish be made to crack.

The finishing should be done with cement. First a thin mortar made of one part of Portland or Rosendale cement and four parts of good sharp sand should be poured over the entire stone work. This mortar should be made so thin that it will run down into the interstices between the stones. After this first coat has thoroughly set a finishing coat made of one part cement and three parts of sand should be put on and worked down with a trowel. Finish off before thoroughly dry by dusting over the top some clear cement and working it in with a trowel. This will give a hard finish and will secure a foundation that is cheap and efficient. While the cement is still soft, it is frequently convenient to strike the circle which will mark the line upon which the staves are to be set. A spike driven in the center will serve as a pivot. Attach to this a bit of string or twine, the length of which shall be one-half that of the proposed diameter of the silo, and to the free end of the string fasten some pointed instrument with which to mark the circle. Now strike a circle the radius of which shall be equal to the length of the string and there is marked out the circle upon which the staves are to be set.

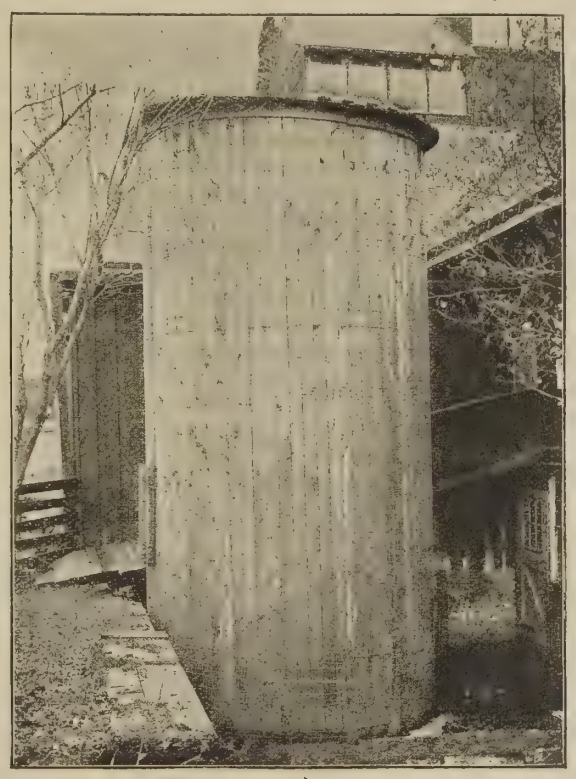

FIG. 1—Showing the use of woven wire fencing for hoops.

MATERIAL TO USE FOR STAVES.

It is probable that no better material can be obtained for the staves than Southern cypress. This, however, is so expensive in New York State as to preclude its use in most cases. Of the cheaper materials hemlock, white-pine and yellow-pine are usually the most available. At the present time hemlock is one of the cheapest satisfactory materials which can be purchased and it is probably as good as any of the cheaper materials. It should be sound and free from loose knots.

PREPARATION OF THE STAVES FOR THE SILOS.

If the silo is to have a diameter of 12 feet or less, the staves should be made of either 2 x 4 material unbevelled on the edges and neither tongued nor grooved, or of 2 x 6 material bevelled slightly on the edges to make the staves conform to the circular shape of the silo. If the silo is to have a diameter of more than 12 feet the staves should be of 2 x 6 material and neither bevelled nor tongued and grooved on the edges. If the staves are left perfectly plain, then when they are set in place and drawn together the first point of contact will be the inner edge, and the tighter the hoops are drawn the closer will become the contact of the staves at the inner edge. If it is impossible to purchase material for staves the length of which shall be equal to the desired depth of the silo, then shorter staves may be used and set up according to the method hereafter described. The staves should be surfaced on the inside so that a smooth face may be presented, which will facilitate the settling of the silage. Whether the outside of the staves shall be planed is a matter of taste, but if hemlock is used the handling of the staves will be found much easier if both sides are planed.

SETTING UP THE SILO.

There are several methods of procedure which may be followed in setting up the silo. Fig. 2 shows a cross section of one method of construction. The posts (a a a) should be of 6x6 material, and run the entire length of the silo. These should be first set up vertically, and stayed securely in place, and then they may be used as part of the scaffolding; they will also serve to give rigidity to the staves, as the work of setting up progresses, and when the roof is put on, the plates which support the roof may be laid on these posts. The scaffolding may be constructed by setting up 2x4 scantling in the positions shown in Fig. 2 as b b b b. Boards nailed from these 2x4 scantling and to the 6x6 posts will form a rigid framework across which the planks for the scaffold platform may be laid. Before the scaffolding is all in place, the staves should be stood up within the enclosure, otherwise difficulty will be experienced in getting them into position. Some caution needs to be exercised in working on the scaffolding, that the planks do not tip, but with ordinary care there need be no danger. The first stave set up should be made plumb, and should be toe-nailed at the top, to one of the posts originally set.

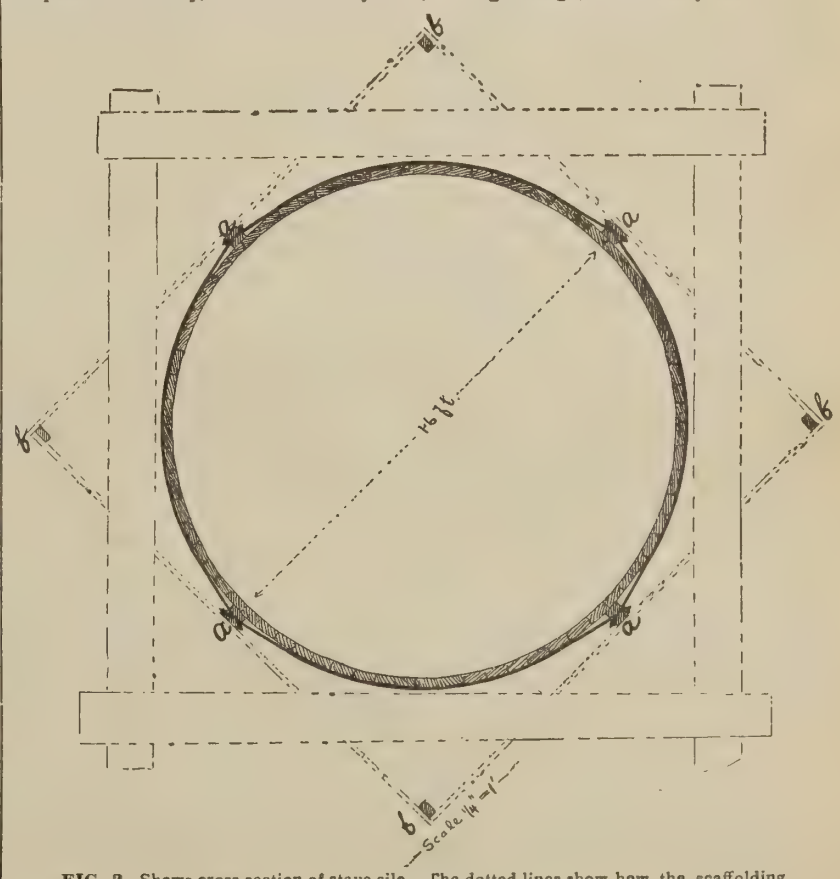

FIG. 2 —Shows cross section of stave silo. The dotted lines show how the scaffolding may be put up.

If one man works at the top of the staves, and one at the bottom, with another man to assist in raising them in position, they may be set up very rapidily. Immediately a stave is set in place, it should be toe-nailed at the top to the preceding stave set. It has been found that the work of setting up and preserving the circular outline may be materially aided by the use of old barrel staves.

Fig. 3 shows how the barrel staves are used. If, when the silo staves are put in place they are toe-nailed securely to the ones previously set; if they are fastened firmly to permanent upright posts (a a a a Fig. 2;) if the barrel staves are used as directed above, the silo will have sufficient rigidity to stand until the hoops are in place. As the staves are set up, the level or plumb should be used occasionally to determine if they are being set vertically. The 6x6 posts mentioned as being first to be set in place are not a necessity, they are a convenience.

SPLICING THE STAVES.

If it is desired to build a silo 24 to 30 feet or more in height, it will often be found impracticable, if not impossible to secure staves the full length desired. Where this is the case a joint or splice may be made.

HOOPS FOR THE STAVE SILO.

The hoops for the stave silo are usually made from five-eighths inch round iron or steel rods. Cheaper substitutes have been used and given good satisfaction. Cut No. 1 shows a silo erected at Cornell University, in which common woven wire fencing was made to serve as hoops. The staves were of 2x6 hemlock, 24 feet long, with edges neither matched nor beveled. The silo was filled directly after completion, and was satisfactory in every way.

Where the round hoops are used, it is well to have each hoop in from three to four sections. For a silo 12 feet in diameter, three sections will be sufficient, while for a silo 16 feet or more in diameter, the hoops will handle more conveniently, if they are in four sections each. If the method of construction shown in Fig. 2 is followed, then the hoops will need to be in four sections each, the ends being passed through the upright 6x6 posts, and secured by heavy washers and nuts. A chisel should be used to sink one edge of the washer slightly, so that the strain upon the nut will be squarely in line with the direction of the pull. If the upright posts are not used, then a convenient way to secure the hoops is by means of the cast iron lugs as shown in Fig. 4. The hoops should be long enough, so that they can be let out if it becomes necessary, after the silo is filled and the strain becomes great

The bottom hoop should be about six inches from the base of the silo; the second hoop should not be more than two feet from the first; the third hoop two and one-half feet from the second, the distance between

THE fourteenth annual meeting of the Holstein-Friesian Association of America will be held at the Iroquois Hotel, Buffalo, New York, on Wednesday, June 7, 1899, at 10 a. m.

OUR occasional correspondent, Mr. C. E. Chapman, of Peruville, N. Y., who is much interested in the American Cheshire Hog, which bids fair to become the "bacon hog" of the future, and devotes special attention to raising the choicest varieties of potatoes, plants, etc., has an interesting catalogue of his specialties which may be had on application.

NEVER in the history of the country was there so large a consumption of milk per capita as at the present time. No counterfeit substance has been found to drive the honest article out of the market, as in the case of butter, and so the cow holds the first and rightful place in consumption.

As an illustration of the rapid increase in milk consumption, the Oregon *Agriculturalist* states that it will take 1,000 more cows to supply the city of Portland than were needed last year.

LINE FENCE RELIGION.

There are but few vexations connected with farm life that are greater than living alongside a neighbor who is slack-twisted in his moral and manly make-up and so neglects to keep up his share of a good line fence. A man who will not restrain his cattle from injuring a neighbor is yet largely a heathen, no matter how much religion he may profess. Years ago there lived in New York two farmers. One, Captain Gray, as he was called, was a shiftless, negligent man about his fences. He was excessively pious, however. Adjoining him lived Uncle Jake Shultz, a vigorous Mohawk Dutchman, who was every inch a farmer. His fields, fences, buildings and cattle were always in prime order.

Uncle Jake, as well as other neighbors, had suffered much injury and annoyance from Captain Gray's cattle, owing to his (Gray's) poor fences. One Sunday morning, Gray was seated on his front porch reading the Bible. Uncle Jake, who was on his way to church, stopped and delivered the following message:

"Cappin Gray, you tink you got lots of religion. How can dot be? Dere you sit, mit der Bible in your hand, der devil in your heart and your cattle in my corn. Such kind o' religion ish a humbug."

We agree with Uncle Jake.

CONSTANT FRAUD.

Levi Wells, Dairy and Food Commissioner of Pennsylvania, says that his agents have discovered that not only has embalmed beef been brought into the state for sale, but that Pennsylvania butchers have been buying chemicals to freshen stale meats. This practice began in Philadelphia, and Mr. Wells fears that it has spread over the State, because chemical companies have had agents on the road selling the stuff, which is put up in packages bearing directions for its use. As Mr. Wells points out, the practice of applying preservaline to meat is a dangerous one. A very small quantity is likely to injure the stomachs of delicate persons and children, and in the hands of men unskilled in its application, the acid could easily be used in proportions dangerous to every consumer of meat. The commissioner believes that the suits already entered will have a strong tendency to keep doctored meat out of the state and stop similar practice in Pennsylvania; but consumers should satisfy themselves that the meat they buy is not treated with acids. A little judicious investigation of their butchers on the part of patrons will help to discourage the practice.

Some day we hope the farmers and consumers of this country will rise in their might and drive all these food swindlers out of existence. They flourish to-day as they do by virtue of the apathy of the farmers. If every farmer or even one half of them would speak out as they ought to these frauds would cease.

Instead of being masters of the men they send to congress and to state legislatures, they obediently follow the crack of the party whip and allow these same bosses to grow rich in many cases protecting oleomargarine and other frauds. Where is the old time American independence of character that Daniel Webster once so proudly boasted, "belonged to the American farmer"?

Public officials, who try to do their duty, too often are voted out of office by farmers who cannot see anything involved but their party.

FATTENING HEIFERS.

On page 257 in last week's issue, Mr. Geo. R. Crehore discusses the doctrine of allowing heifers to get fat, and asks the question: "Do these gentlemen never turn their heifers on good pasture? And if so, do they never get fat?"

There is this to be said to the above question. Pasture grass is a perfectly balanced ration, provided it is fresh and moderately short. It has a protein content of 1 to 4 of carbohydrates. Protein, in its physical effect, is a nerve and muscle supporter and developer. The mammary organs are composed of a wonderful tissue of nerves. Under such food, they grow and expand even if the animal does take on flesh.

But corn meal and other carbonaceous foods seem to exercise a totally different effect upon the mammary organs. Under such influences, the flesh making or fattening tendency is developed and the mammary organs grow weaker and less developed. Such is the practical effect of the two foods on young heifers, as has been observed by dairymen and so recorded for a hundred years.

The young heifer can easily be made or unmade as a future cow by the character of her feed and handling. There is fat and fat. Many dairymen have observed that with cows of a low dairy temperament, that are not strongly bred and developed towards milk making, if they are fed, for instance, corn meal heavily, they will commence taking on flesh, and shrink in their milk more and more as they increase in flesh.

The specific dairy temperament is first a thing of breeding and second of feeding and handling.

We breed towards a better cow and must follow up the breeding with true dairy handling and feeding, else we fail to develop that which we had implanted by breeding.

In our study on this important question several years ago, we took a three-fourths grade Jersey cow of very specific dairy temperament and fed her for three months on a ration of hay and corn meal and bran. To see how far we could go with this cow in feeding a fattening food, we gradually increased the corn meal until we were feeding her fourteen pounds a day. So strong and decided was the dairy temperament in her that she took this heavy, fattening ration and turned it into milk without increasing her flesh perceptibly. But had this cow been fed on carbonaceous food when a heifer, and made to keep fat on the same, the dairy temperament in her would have been so weakened, or changed, as to produce a totally different result.

We agree with Mr. Crehore in the last paragraph of his communication, to this extent, that the first thing to do is to breed in a "tendency to do dairy work." This means to establish a strong vital dairy temperament. But we must remember, that until developed by actual maternity this "tendency" is in embryo, and it is often easily spoiled.

The Making of a Good Cow.

ED. HOARD'S DAIRYMAN:—We have many cows, and the average production is hardly up to cost.

WHAT IS THE COST?

Dr.

Silage @ $1 50 per ton	$.03 cts.
Grain @ 16 00 per ton	.08
Hay @5.00 per ton	.02½
Labor	.02
	.15½ cts.
200 days @ .15½	31 00
165 days Pasture	6.00
	$37.00

WHAT DO WE RECEIVE?

Cr.

Milk, 1825 qts. @ 1¾cts.	$31.93
Profit and Loss	5.09
	$37.00

The recent bulletin from Mich. Agricultural College indicates that some money can be made even with scrub cows, by a better method of care and feeding, but I am reminded of the question of the boy, "Father, you feed me and the pig, potatoes, don't you?" "Yes." "Why don't the same food make two pigs then, or two boys? Why does it make a boy and a pig?"

The serious question is why will some cows make a profit and others a loss on the same feed?

It is not a question of breed. The proportion of unprofitable cows among the full bloods is as great as among the much abused scrub which is only another name for grade stock that inherits some good qualities as well as all the poor ones of their illustrious sires.

It is not a question of feed. I know men that have fed up farms, and been sold out on a mortgage.

It is largely the result of improper treatment, the first and second years of the calf's life. But few have a correct idea in their mind of what they want the cow to do, the best conditions for most favorable results, or how to obtain them.

They simply put feed before them and let them "come up". Many do not take the trouble to examine the teeth, udder, teats, or look at the shape, but raise the calf because it's from old "Spot". A weak calf shows it, and should be discarded. You can, if successful with stock, feed for vitality, but born vitality is more satisfactory.

What do we want this calf when grown up to do? Convert a large amount of food into milk, and produce offspring, become both a machine and a mother.

A machine to be profitable must be on a large scale. The cow has to grind up about eight tons of fodder per year. This means that a healthy stomach is required. From her habit of eating the coarse food and then re-chewing it, a large storage capacity is required to hold the large amounts needed to produce large results.

The cow must have correct habits and use the food for the purpose we want her to.

All of these essential conditions are largely the result of proper feeding the first two years.

The stomach of young animals is very sensitive to change and when once weakened by any cause never fully regains its natural power. A calf which has had one bad case of scours, in after life will not stand high feeding. A calf which is not supplied with good, forcing food, never becomes a great cow, because its powers of assimilation have not been developed.

The natural milk of the mother will not cause scours and will develop the calf.

Calves that have never sucked and are born healthy will drink the first attempt. They should have it for two weeks. Not much danger of trouble if the pail is kept clean and the milk is fed direct from the cow.

The trouble comes when the new milk begins to fatten (bad habit), fails to distend the stomach (no storage capacity), and skim milk and other foods are resorted to, to counteract these tendencies. A few men are able to 'finger' the milk and guess at the amount, so as to always have it warm enough and not too much. Too cold or too much milk is the only cause of stomach trouble in a vigorous calf. Better to own up and be a mechanical feeder, i. e., use a thermometer and measure, than to go on aiding in filling the world with poor cows.

Pure skim milk is not a good food for developing a good calf. Too much of it is required, for the first two months, to furnish all the elements needed and the stomach is overloaded. A little ground flax seed and oil meal added to separator milk will obviate the difficulty. The stomach should be extended partly by dry food instead of exclusively by food in liquid form, and wheat bran and clover hay will make growth, as well as perform this office. Their use gives strength and health while getting the distension; slops give scours.

The best calf in the neighborhood usually belongs to some mechanic or other laborer whose wife feeds it hay and a small warm mess of dish water and wheat middlings twice per day all summer, in place of milk.

At six months the calf should look like a cow in form, and grow every day.

Calves should be bred to calve at twenty months, and then the milk giving will prevent their fattening which would take place at that age if dry. They should grow every day from birth till mature, but never fatten. No dependence should be placed on the pasture the first year. Better not go out than to stop growing. They should be fed so as to produce a full flow of milk and still continue to grow in weight and ability to consume food. The demands of motherhood produce an appetite for food, and the whole system is active.

Every effort should be made to stimulate growth, milk production, and capacity, without regard to money return for the first two years. A cow heavily fed may not be a cow well fed. A cow must be brought to a high production within the first two months after calving, or failure will result for that year. Keep feeding and do not breed for second calf early, but milk a year with first calf. If the cow shrinks in her mess from any cause, she does not fully recover, till after next calf is dropped, and if a heifer, may never.

A single mistake at any critical period will undo all the work done, and to rear a calf so that she will be a large and persistent milker, is more difficult than painting a picture. The few really extra good cows prove it.

Peruville, N. Y. C. E. C.

What Attracts Boys.

How to keep boys on the farm is as much a question in the south, as in the north and west. Speaking of this the *Western Agriculturist* says:

While scieentific agriculture is an inviting field for the farmer's sons, the highest achievement is attained by the breeders of pure bred stock. Note the large number of public sales the past year, where $10,000 to $20,000 worth of surplus young stock was sold, and the breeding plant retained to keep up the supply of pedigree stock for the regular annual sale. All kinds of pure bred stock are in demand, and nothing will interest the boys like the pedigree stock that sells at good prices. There is a commercial business-like fascination about it, that will interest the boys and keep them on the farm Scientific breeding of the improved breeds is a benefit to the community, to the state and to the nation, and adds millions of dollars to the wealth of the country, and brings prosperity to the farm.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed f orm or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained by some, that the fat in the milk comes, largely,, from the crude fat in the food, but ithas been demonstrated that it is not absolutely necessary, for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

CROP ROTATION FOR MAINE.

Would you recommend a rotation crop of corn, peas and oats, and clover for this section of Maine? My land is rocky and hilly. I intend to keep twenty cows on a thirty acre farm. Will plant ten acres of corn, pick ears and put small ears and stalks in silo. Do you think I can keep twenty cows on thirty acres? I have two silos.

Monroe, Me. G. M. T.

P. S. Will the rotation crop kill witch grass?

The rotation suggested would be all right, except for the "rocky and hilly" character of the farm, and this is mostly a matter of comfort and convenience. We are not much accustomed to working such land and possibly magnify its disadvantages. Ten acres of corn, with ten acres of clover and ten acres of oats and peas will furnish all the roughage necessary for twenty cows, and with such a combination the amount of grain required will be reduced to a minimum.

The extermination of witch grass will depend more upon the thoroughness of cultivation than upon the kind of crops.

TRY SOY(SOJA) BEANS.

I have ploughed an orchard of 6 acres, and the trees are well apart. I wish to sow something in this orchard for my cows for winter that will help to take the place of my grain ration, and take as little from the ground at the expense of my trees as possible. Grain in this vicinity is high in price, and anything grown upon the farm that will offset a part of this expense, will be greatly appreciated as an addition to what I get every week through the columns of your paper.

Boston, Mass. G. E. S.

We should try, at least on a part of this ground, the soy (soja) bean. It has been raised at the Hatch experiment Station in Massachusetts for several years and for the variety to use and method of cultivation for the climate of that state would recommend that inquirer to confer with the officers of that station. There is yet ample time for sowing this crop. If it was not already so late in the season we would suggest oats and peas for balance of the lot, but as it is, consider corn about the safest and most profitable crop.

See elsewhere in this issue commendation of soy beans by correspondents.

PROF. KING'S PAPER ON BARN BUILDING AND VENTILATION.

In reply to a Kentucky inquiry, we may say that the above paper will be published in the forthcoming report of the Wisconsin Dairymen's Association, the "copy" for which is all ready for the public printer. The volume will probably be ready for distribution in four to six week, depending somewhat upon the convenience of the printer. If practicable to do so, HOARD'S DAIRYMAN will secure a copy of the paper and accompanying diagrams for earlier publication.

MILK FORMING BEFORE PARTURITION.

I am only a 25 cent subscriber, but will be a dollar one as soon as my time is out.

I have a two-year-old Short-horn grade heifer that will drop her calf sometime in October. Her bag is swelled taut, but not caked, and she has milk. What will the effect be of milking her? G. M. T.

Monroe, Mo.

If there is milk in the heifer's udder it should be withdrawn and milking should continue as long as milk is formed. No deleterious results will follow such a course, but very serious consequences might follow if the milk should be re-absorbed by the udder tissues. It is unusual for milk to form in the udder previous to first calf, but such instances have been known.

THE COTTONSEED MEAL QUESTION.

You recommend cottonseed meal as a food to balance rations for cows. In No. 10 of the present volume, Dr. Horne says, it and cob meal are the worst foods known for breeding cows. I have been feeding it and am having trouble getting my cows with calf. Have not exceeded two pounds per day to the cow. Do you think it is the cause?

I have been taking the DAIRYMAN two or three years. Although I live in town and work at my trade, I am milking four cows at present, two and three year old heifers, and get about eighty pounds a day of 5% milk. I want to go on a farm next spring and am picking up a few calves and heifers when I can find one that suits my idea, as I understand the teachings of your paper.

I have one two-year-old heifer that gives twenty-two pounds of 5% milk per day. She dropped her calf in February when twenty-two months old.

Plattsburg, Mo. W. T. H.

"When doctors disagree, who shall decide?" HOARD'S DAIRYMAN in all its departments is edited upon the theory that no man, and perhaps least of all, any of its editors, is infallible. Its several editors are accorded equal privileges with its occasional correspondents, each to give his personal views freely, and this upon the theory that its readers are intelligent people, capable of weighing evidence and argument, and coming to conclusions in regard to the questions discussed in its columns with as much certainty as upon other questions. The present writer cannot conscientiously say, for example, that Dr. Horne is wrong in his views concerning cottonseed meal and corn and cob meal, but he can say that neither the evidence on these subjects nor the reasoning adduced has as yet sufficed to lead him to concur in the Doctor's conclusions. True, the Doctor has had a larger personal experience and a wider personal observation than the writer, but that is not sufficent reason for surrendering one's personal judgment, or suppressing it when occasion calls for its publication. One of us places most reliance upon a certain line of evidence, and the other finds his justification in other facts, and if either was not true to his own convictions, he would not be a faithful exponent of the principles which have guided HOARD'S DAIRYMAN in all the years of its publication.

Until better advised, the present writer will continue to advocate the rational use of cottonseed meal and corn and cob meal and silage in the department of feeds and feeding, following in this respect the teachings of his own experience and that of numberless other dairymen and experimenters. The time may come, and possibly at no distant day, when further facts brought to his attention will compel him to modify his present views and accept those held by his collaborator. Meantime let the reader follow neither one of us blindly, whether in regard to those matters wherein we agree or those wherein we disagree. Rather, let each one read, think and act for himself. We cannot all agree in politics or religion, and it should not seem strange that there are differences of opinion in regard to matters of diet and what are suitable feeds for milch cows.

PEAS AND SORGHUM.

I have 15 or 20 acres of good land that I wish to seed in cow peas, sorghum or millet hay for milch cows. Land adapted to either of the three crops mentioned, but cannot be seeded before about July 1st. Which of the three would you recommend?

Virginia. F. A. M.

Use sorghum or kafir corn with the peas. Kafir corn is advocated by many because the stalks are sufficiently strong to act as a support for the pea vines and thus prevent lodging. Sorghum would probably act in the same way.

AS TO MILK FEVER.

Is a cow liable to have milk fever when she calves, if she has never been dry? What is the best remedy for it? Is it best to milk a cow right up to the time of calving?

St. Francisville, Ill. MRS. J. D. B.

It has been the general belief, hitherto, that cows milked up to the time of parturition, were exempt from milk fever, but it must be admitted that the wisest among us have confessed that there was very little positive knowledge on the general subject or most of its phases. A new theory on the subject has recently been advanced (for which see DAIRYMAN of May 12, page 254), attributing the origin of this malady to ptomaine poisoning, but whether from the udder or the uturus is uncertain, and if further investigation shall confirm these views, we may have to be less positive about the immunity of constant milkers.

See the article referred to for remedies.

Whether it is best to milk a cow continuously will depend very much upon the cow. If she will dry off readily we prefer to give them six to eight weeks' rest, but under no circumstances less than four weeks. It is unwise to force a persistent milker to go dry; increase the feed to compensate for the additional demands upon the system and continue the milking.

PRESERVING AND TAKING MILK SAMPLES.

For making composite test of milk, what is the best preservative, and what is the best to take the sample with? How long can the milk be kept in summer time without injury to the test? N. H. W.

Necedah, Wis.

The best preservative, for general use is powdered bichromate of potassium, about 8 grains per pint of milk. The above amount will keep a pint of milk one to two weeks.

The method that is the least liable to cause incorrect sampling is that of the Scovell sampling tube. This consists of a simple tin or brass tube that can be closed at the bottom by a valve. It is filled by being lowered into a can of milk. The valve at the bottom is closed by pressure, and the tube full of milk is removed. It will furnish a correct sample, even if the milk has been standing some time.

Although samples can be kept two weeks, it is advisable, in the interests of accurate work, to test oftener, once a week at least. The oftener the sampling and testing is done, the less liability there is to errors in the work.

SILO QUESTIONS FROM ILLINOIS.

What kind of corn has proved best for silo?

The largest variety that will mature in your climate.

When best time to plant?

When the soil is in best condition, and danger of frosts is well past.

When best time to plant the ensilage corn?

It is not a bad plan to plant some at different dates, so that the whole will not mature at the same time, and thus necessitate hurry in filling the silo.

A MAINE RATION.

I wish you would formulate a ration for me, in your next issue, out of the following: Timothy hay worth $5 per ton, bran $20, cotton seed meal $24, corn meal $19, oil meal $28. You may leave out oil meal, if you think it too expensive. My cows are of large size and fresh in milk.

I like the DAIRYMAN very much.

Union, Maine. H. B. B.

If the cows are to have only the feeds named, and are in fair flow of milk, they could not be expected to do their best with much less than the following:

FORMULA FOR RATION.	*Dry Matter.*	*Digestible Nutrients*		
		Protein.	Carbohydrates	Ether Extract
20 lbs. timothy hay...	17.36	.56	8.68	.28
6 lbs. bran.....	5.29	.75	2.32	.18
2 lbs. corn.....	1.78	.16	1.33	.09
2 lbs. cotton seed meal	1 84	.74	.34	.17
Totals.....	26.27	2.21	12.67	72

This is an expensive ration, but it never pays to stint a cow in her feed, and it seldom pays to keep a poor cow.

We hope our friend will prepare for next winter by having something better and cheaper than timothy hay for roughage. We think he should have a silo, and some clover or oat hay.

GALVANIZED IRON IN THE CREAMERY.

I should like to know if galvanized iron tanks and pails can be safely used in the dairy. If not, why not?

Can plastered walls in a dairy room become so impregnated with organic matter as to endanger the quality of the milk by keeping it in the room over night?

Will buttermilk or sour cream, kept in the same cooling tank, in cans, with sweet milk, hasten the souring of it?

Also, will you tell me where milk faucets can be obtained which can be easily cleaned and safely used in milk cans and tanks? This town of Denver, or the dairy supply houses, are too small to keep such things for the use of dairymen, and I presume that many other towns are unable to keep them also, hence the inquiry. F. J. B.

Denver, Colo.

Galvanized iron is not as good as tin for dairy vessels, as it is not so easily kept clean. The oxide of zinc is liable to form a compound with the fat of the milk and the resulting coating is not easy to remove.

If kept clean there is no reason why it cannot be used.

It is possible, but not probable, where the creamery is kept in a cleanly condition. Moreover, such walls should be whitewashed at least once a year, which would go far towards keeping them in a cleanly condition.

No.

Any of the general dairy supply houses will furnish you with a faucet of the kind required.

The Stave Silo.

(Continued from page 267.)

hoops being increased by one-half foot until they are three and one-half feet apart, which distance should be maintained, except for the hoops at the top of the silo, which may be four feet apart. The hoops should be drawn fairly tight before the silo is filled, but not perfectly tight. They must be tight enough to close up the space between the staves, thus preventing any foreign matter from getting into the cracks, which would prevent the staves from closing up as they swell, thus allowing air to enter. To hold both the hoops and the staves in place, during the summer when the silo is empty, staples should be driven over the hoops into the staves. If a sufficient number of staples are used, they will prevent the sagging or dropping down of the hoops, and they will hold the staves securely in place.

The hoops should be watched very closely for a few days after the silo is filled. If the strain becomes quite intense, the nuts should be slightly loosened. If during the summer, when the silo is empty and the staves thoroughly dry, the hoops are tightened so that the staves are drawn closely together; when the silo is filled, and the wood absorbs moisture and begins to swell, the hoops must be eased somewhat to allow for the expansion. If a silo is constructed of thoroughly seasoned lumber, and the hoops are drawn tight before filling, when the silo is filled the hoops must be loosened slightly, or there is danger that the hoops will break or the thread will be stripped.

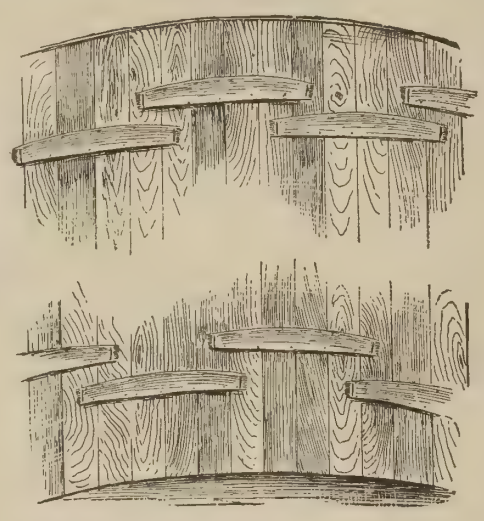

FIG. 3—Shows how barrel staves may be used in setting up a silo; they should be removed before the silo is filled.

DOORS FOR THE STAVE SILO.

The doors should be located on the side of the silo most convenient for feeding. They may be in line, one directly above the other, or they may be placed anywhere fancy or convenience dictates. If doors are placed one above the other, the short pieces of staves should be well secured to the hoops by staples. The lower door should be between the second and third hoops, at the bottom, and other doors will usually be needed in every second space between there and the top except that no door will be needed in the top space as the silage when settled will be sufficiently low to enable it to be taken out at the door in the space below. Plans should be made for the doors at the time the staves are set. When the place is reached where it is desired to have the doors, a saw should be started in the edge of the stave at the points where the top and bottom of the doors are to come. The saw should be inserted so that the door can be sawed out on a bevel, making the opening larger on the inside of the silo. (See Fig. 5). This will enable the door to be removed and put in place only from the inside, and when set in place and pressed down with silage, the harder the pressure the tighter will the door fit. After sawing into the edge of the stave deep enough to admit the end of the saw, the stave should be set in place, so that the side corresponding to c. c. in fig. 5 shall be on the outside of the silo. After the silo is set up, and the hoops have been put on and tightened, the cutting out of the doors may be completed. The size of doors would better be two feet wide by about two and one-half feet long. This will allow the passing through of a large basket, and will make a door of convenient size for handling. Before cutting out the door, cleats 2 inches by 3 inches in length equal to the width of the door, should be made which will conform to the circular shape of the silo. One of these cleats should be securely bolted to the top and one to the bottom of where the door is to be cut. (See fig. 5). After the bolting, the door may be sawed out, and it is then ready for use. When set in place at time of filling the silo, a piece of tarred paper inserted at the top and bottom will fill the opening made by the saw, and prevent the entrance of any air around the door.

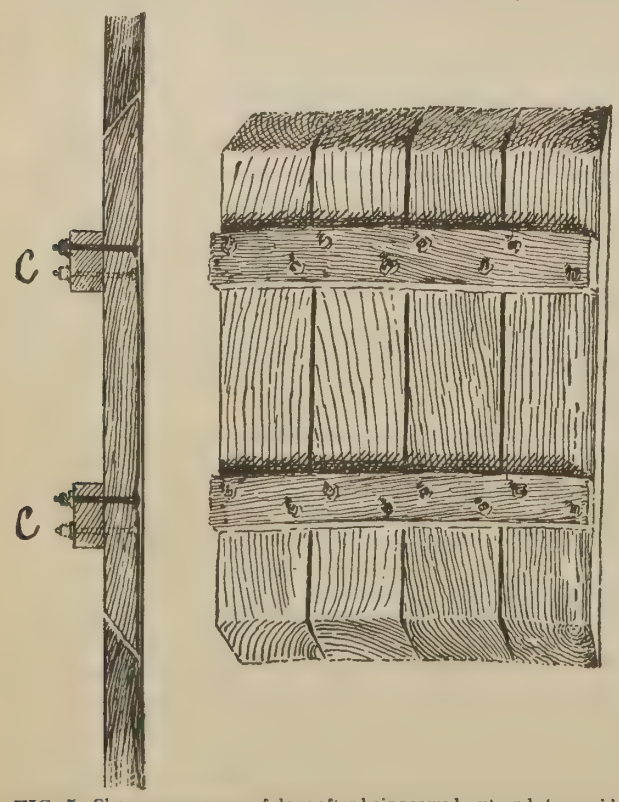

FIG. 5—Shows appearance of door after being sawed out, and shows side view of door in place. The cleets c. c. are on the outside of door.

THE SILO ROOF.

If constructed in the barn no roof or covering of any kind will be needed. If constructed out of doors some kind of roof should be provided. If the method of construction shown in fig. 2 is followed, and the upright 6x6 posts are used, these posts may serve as supports for the plates upon which the rafters are to rest. The roof should have a sufficiently wide projection to protect as thoroughly as may be the walls of the silo from the elements. The plan of roof construction which will prove efficient is shown in fig. 6. It is not necessary that the structure be air tight above the circular part. The gable end which is shown as open in the figure, may be boarded up. In this gable end a door should be provided through which the silo can be filled. The roof should extend from the silo to the barn, so as to cover the space which intervenes, and thus afford protection to the feeder in stormy weather. Another way in which the roof may be put on is shown in cut No. 1. Around the top of the silo was bent and nailed one half inch Georgia pine. This was put on so that a slight slope was given to the roof boards which simply overlap each other.

PAINTING THE SILO.

Whether the silo shall be painted on the outside is simply a matter of taste. If the other farm buildings are painted it would be well to have the silo painted the same as the other buildings. Various paints and compounds have been recommended for the interior. Probably the best paint is common gas or coal tar, put on hot, though it is very doubtful if the interior is improved by painting. If paint is applied to the staves while they are still green, it is likely to hasten rather than prevent decay. If gas tar or paint is applied it should be done after the hoops are made tight, and the staves drawn close, otherwise the paint is likely to enter the cracks and harden and thus prevent the staves from being drawn together. The large silo built at Cornell University was painted upon the interior, a part with gas tar, and a part with a special preparation, and one part was left with no paint; the silage kept equally well in all portions of the silo.—*Cornell University Bulletin.*

THE LUNG QUESTION.

It is said, "that that which we cannot prove, we argue most over," and generally speaking it is true. No one ever heard two men disagree, and much less quarrel over the multiplication table.

Our dual-purpose friends, and all cattle men, who have derived their ideas from a study of the beef outline, are fond of talking about the value of great width between the fore legs, on the ground that such outline indicates larger lung and heart power.

More than this, they are fond of considering this conformation also as an indication of constitution, vitality, power to resist disease, etc. These same people cry down the narrower chest build of the specific dairy form, and have much to say against it as indicating "lack of vitality, weakness of constitution, etc."

All this leads us to ask the following questions:

Is it true that the wide-between-the-legs beef animal has larger lungs, of greater tissue or breathing surface, than the more narrow chested dairy animal?

Has anyone taken the pains to follow these several dissimilar forms of cattle to the slaughter pen, and examine to see which is of the larger breathing power?

In similar manner, has any such comparison been made as to the size of the heart and its "action?"

Do these men who talk so confidently on this matter know "for sure," by anatomical examination, what they are talking about?

The same talk is heard among the breeders and owners of draft horses. They have the same remark to make about the deep wide chest, indicating greater lung and heart power. Is there any truth in this notion about horses?

In the race horse, for instance, we often see narrow chest formation. Some will say, "the fore legs look as if they come out of the same hole." Yet does this race horse build indicate a lack of lung and heart power?

In running a mile race the race horse has to exercise both lungs and heart to a greater extent than a draft horse will in a full day of hard pulling.

So in dairy cattle, are there any sound, well established facts for saying, that they have less lung or heart action than beef cattle?

We know of a certainty that beef cattle with their big, round briskets are just as liable to tuberculosis, under like exposure, as are the more "narrow chested" dairy breeds.

It occurs to the DAIRYMAN that on this "lung question," as well as the external build or shape of the barrel, there has a lot been said that is founded on mere notion or theory.

Thorough students of both beef and dairy breeds know how little real demonstration of the truth there has been by actual physiological study and recorded statement.

Dr. J. M. M. Kitchen spoke very close to demonstrable truth last week, on page 232, where he says:

A small well used pair of lungs, or any other tissue in the animal is not so subject to tubercular diseased action, as is a large but under used part. The ability of any tissue to resist such invasion, depends upon its healthful state, the force of the blood current coursing through it, the completeness of its nourishment by a well balanced blood supply, the nervous energy directed to the parts, the thoroughness of the oxygenating process in the tissue, and the impure or imperfect air.

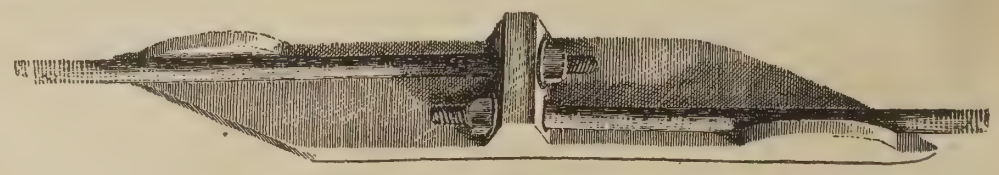

FIG. 4—Shows how the ends of hoops may be secured.

"Want of Watchfulness Makes the Thief."

Many cases of poor health come from want of watchfulness. But if you keep your blood pure no thief can steal your health.

The one effective, natural blood purifier is Hood's Sarsaparilla. *It never disappoints.*

Impure Blood—"Five years I suffered with pimples on face and body. Hood's Sarsaparilla cured me permanently. It also cured my father's carbuncles." ALBERT E. CHAST, Tustin City, Cal.

Catarrh—"Disagreeable catarrhal droppings in my throat made me nervous and dizzy. My liver was torpid. Hood's Sarsaparilla corrected both troubles. My health is very good." MRS. ELVIRA J. SMILEY, 171 Main St., Auburn, Maine.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Not a Preservative but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION MILK COOLER-AERATOR. It does its work perfectly and its use doesn't violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

GRADING UP.

An Oregon paper notes the fact that Mr. E. W. Gaptil, of Coos Co, in that state, has been paying special attention to the grading up of his cows. When he commenced, the average product per cow was 141 pounds a year. Now it is 252 pounds of butter fat or the equivalent of 294 pounds of butter.

It may be said that he did not secure this result by following out "dual-purpose" ideas of breeding. This grading up of cows to larger dairy power and profit is a simple affair. But simple as it is, the great majority of the farmers in the United States, who keep cows for dairy purposes, have much to learn concerning it. When one can ride through a community in Wisconsin, for instance, where the farmers have been patronizing cheese factories and creameries for twenty years, and not more than one in seven has a registered bull, of a dairy breed, at the head of his herd, we can get some idea of how much good breeding sense has filtered down through that community and into the judgments of its members in the fifth of a century.

Hundreds of dairy farmers in Wisconsin have brought up their herds to a point much in excess of what this Oregon farmer has done, yet his record is a most excellent one We have seen such men repeatedly with neighboring farmers right along side of them who did not believe a word of what the successful man was doing. Such instances are constantly found in creamery work, where every man must come to a common record of production. But, somehow, the more successful record is not brought home sharply to the comprehension of the dull and indifferent neighbor. There is no publication of each patron's result per cow, so all can read and compare. But it is strange how contented some men can be with poor cows and starvation results.

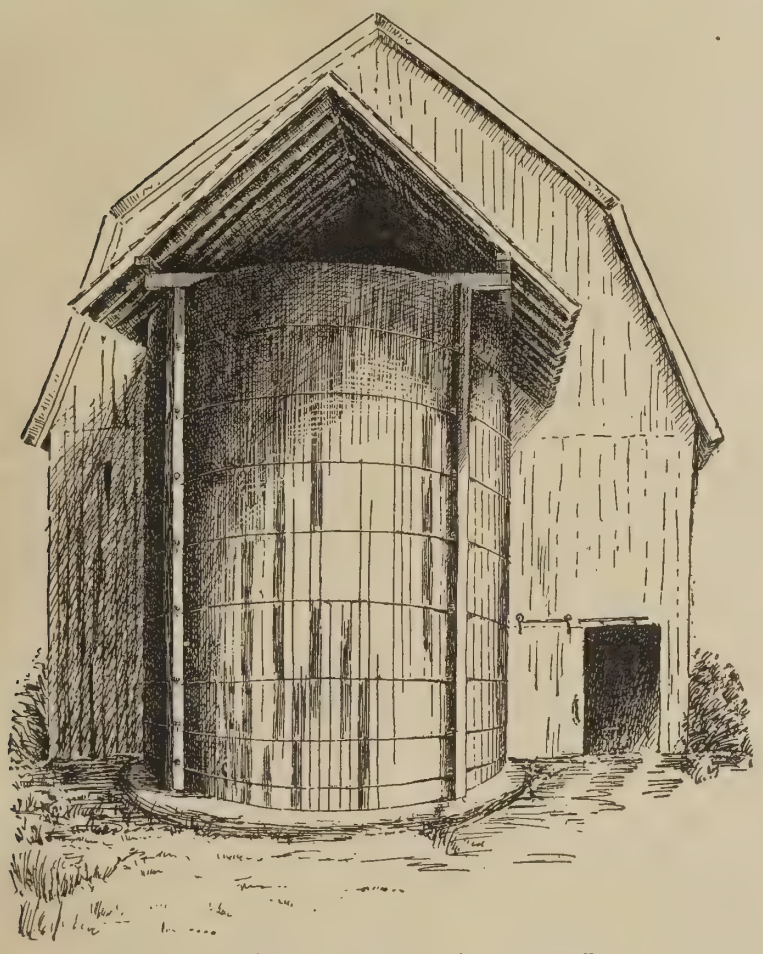

FIG. 6—Shows p n of construction of stave silo.

Why Are Eggs so Scarce?

ED. HOARD'S DAIRYMAN:—No great industry in this country is as much neglected and as little understood, as egg and poultry culture.

It is true we have a few dealers scattered through the country, who have made a scientific study of the nature habits and requirements of the hen, and some valuable books have been written on this subject, but they do not find their way into the hands of the farmer; perhaps not one farmer in five thousand has ever read a book on poultry raising. Notwithstanding the above fact, the industry has grown, perhaps, more rapidly in the last decade, than any other in America. What would it be if the farmer understood, and put into practice, the best information we have on this subject?

It seems to be the prevailing opinion of dealers in the West, that the exceedingly severe cold winter is the cause of the light crop of eggs this spring. It is to be hoped that some good will result from the scarcity and high prices of April eggs. It may stimulate the farmer to build warmer hen houses and be a little more liberal with proper food. It has been said that wheat fed to chickens will yield two dollars per bushel. No doubt the greatest of all mistakes, is in not cleaning out the hen house daily instead of once in five years. The normal temperature of the hen is 108 degrees, ten degrees higher than the human body; hence their liability to become diseased if not kept clean.

Chicago, Ill. J. E. KEITH & CO.

A Summer Resort For The Cow.

ED. HOARD'S DAIRYMAN:—The secretion of milk being in a large measure due to the nervous condition of the animal, it is important that we give her comfortable surroundings where she can recreate and chew her cud. Last summer the Kansas Agricultural College herd was pastured one-half mile north of the college barn and in order to furnish protection from the hot sun and the flies a small thicket in the lower end of r draw was opened up. The cows ignored this act of kindness and betook themselves to the top of the highest bluff, and there where the cool breezes would strike them, recreated with seeming satisfaction. The stiff breezes, usually found on such high spots, had the effect of driving away many of the flies, and left the cows free to manufacture pasture grass into milk. Any dairyman having a high knoll or bluff accessible to his cow pasture would do well to fix it as a summer resort for his cows. If possible, select a bluff where trees will furnish plenty of shade. If that be impossible an open shed will keep off the hot sun. While the cow is thus enjoying her summer outing, she will at the same time be hard at work returning thanks to her owner in the form of butter fat.

D. H. OTIS.

Kansas Experiment Station.

The Dilution Method of Cream Raising.

There are places in the state where there has been a good deal of talk of late about a "new" method of raising cream. It is sometimes called the dilution method.

The process is an old one which has fallen into disuse, but which has recently taken on a new lease of life, largely through the efforts of several concerns which are selling cans specially devised for the purpose. These cans vary more or less in minor details, which, however, do not appear to affect the character of their work. The process is the same in each case. The milk is diluted with an equal or with a greater bulk of water; the mixture is allowed to stand two hours or more, and is then skimmed by drawing off the skim milk

The advantages claimed for the method are reduced cost, lessened labor, durability and the obviation of ice storage and use. Incidentally it is stated that the cream is got cleaner than with the creamery, and that if the separator is rightly managed, all the cream will be obtained.

Some interesting tests of this method have been reported recently by the Vermont Experiment Station. This "new" dilution method, as any one can see, requires more tank room and depreciates the value of the skim milk. Besides this the Experiment Station tests show that the milk does not cream so well.

Over a hundred trials of two different sizes of the "Wheeler Gravity Cream Separator" were made at the Vermont station The "Gravity Separator" left in the skim 13% of the fat of rich Jersey milk, 40% of the fat of Ayrshire milk, and 17% of the fat of stripper milk, mostly Jersey. The centrifugal separator left in the skim milk between 1 and 2% only of the fat. The centrifugal separator, moreover, was able to extract cream from the diluted skim milk from the so-called "Gravity separator".

These results speak for themselves. The cans are less efficient then centrifugal separators, less efficient than the best forms of deep setting apparatus, and no more efficient on the average than the old fashioned shallow pan. It does not seem as if the convenience, simplicity and cheapness of the apparatus compensate for its lack of efficiency, or that it ought to compete successfully with a centrifugal separator. The latter costs more, but it saves more of the butter fat and is undoubtedly the cheaper apparatus in the long run.—*Ex.*

Profitable Feeding.

Double Price for Grain Fed to Dairy Cows.

"Any farmer would be glad to sell his corn and oats at twice the market value," says the *National Stockman*, "and while this is not possible in the ordinary way of marketing, it is perfectly feasible, if the grain be fed to a good dairy cow. There are certain conditions necessary to insure this, it is true, but they are not out of the reach of the farmer with small means. Warm stables, plenty of pure water, well above freezing temperature, plenty of good wholesome food and kind treatment—these are within the reach of any one who owns one or more cows."

Just a Cough

Not worth paying attention to, you say. Perhaps you have had it for weeks.

It's annoying because you have a constant desire to cough. It annoys you also because you remember that weak lungs is a family failing.

At first it is a slight cough.
At last it is a hemorrhage.
At first it is easy to cure.
At last, extremely difficult.

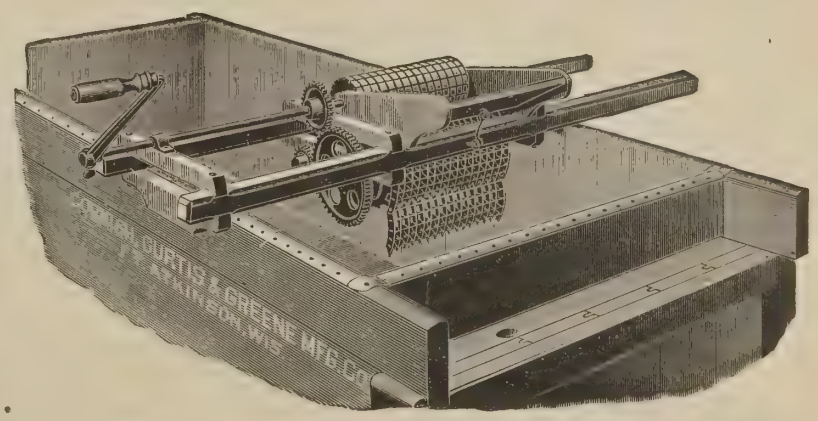
Ayer's Cherry Pectoral

quickly conquers your little hacking cough.

There is no doubt about the cure now. Doubt comes from neglect.

For over half a century Ayer's Cherry Pectoral has been curing colds and coughs and preventing consumption. It cures Consumption also if taken in time.

Keep one of Dr. Ayer's Cherry Pectoral Plasters over your lungs if you cough.



Shall we send you a book on this subject, free?

Our Medical Department.

If you have any complaint whatever and desire the best medical advice you can possibly obtain, write the doctor freely. You will receive a prompt reply, without cost.
Address, DR. J. C. AYER,
Lowell, Mass.

PIGS Eligible to REGISTRY, and First Class Stock, at Reduced Prices. Chester White, Berkshire, Poland-China and J. Reds. Thuroughbred and Grade Guernseys. Also Poultry. W. B. HARVEY, West Grove, Pa.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00.**

Note and Comment.

Old Slicker.—Price of Milk and Cows, Silo Corn, Yield and Cost of Protein.—Peas and Oats in Ohio.- A Milk Trust in Ohio.

ED. HOARD'S DAIRYMAN:—To an inquiry "What has become of Old Slicker?" we reply that the old cow is alive, and right at it this year as usual, and doing pretty fairly well. She freshened January 1st, last, and is now 127 days in milk, and last night and this morning gave 43 pounds of milk. She has blue grass pasture, and four pounds of grain a day, one pound gluten and three pounds fine bran. As milk has sold here all winter, up to May 1st, at 11 cents, it is seen that at factory prices, her milk for 120 days would be worth looking after.

This year, the first time in her history, Slicker gave me a heifer calf; in markings and form is the counterpart of herself, and is now a lusty calf. If there is anything in "signs," Miss Alahoe will make a fine producing cow. In due time Miss Alahoe will offer her picture to the public.

***

The posting of 90 cent milk notices every where in this section for May, has given dairying an encouragement not known about here in several years. Last year, the May price was 60 cents per 100, so that a gain of 33⅓ in a year is an advance in raw material not shared in, except by a few of the "industrials," and many a farmer is heard to say, that the prices would have been no better than last year, if is was not for the city cream men, who—while not claiming any spirit of competition—are buying milk on city cream basis, and not Elgin or Little Falls. The regular milk buyers are forced to pay going rates or—well look on and decry expansion—of the city demands.

Cows have not been so high in price since the war in '64, and it costs now 50 cents to even look at a good cow. A year-old heifer is worth $20, with or without breeding. A herd of thirty-eight to forty-five cows went by yesterday, that certainly showed an advance in prices of 100% in a year, and if I am any judge of cows, about all the owner will ever get in return from them, will be the pleasure of feeding them for the sake of their company, a proceeding, which, by the way, is quite popular with scores of dairymen in all sections of the country.

***

Prof. Haecker always writes entertainingly, and with much instruction, and in April 28th DAIRYMAN, brings out a point which, from my limited experience, I think him very largely in the right; while it is "against the teachings." As I recall twelve years of silage feeding, I do not remember that my cows performed any better at the pail, with silage heavily eared, than with a silage ration more thickly grown, so that only nubbins were found instead of ears. The same bran ration sufficed with the light grained silage, and it was commented upon at the time, but thinner seeding and more ears was thought to be the thing, and so back to ten quarts of seed to the acre was the rule again, though we are sure that there was several more loads of silage to the acre with the thicker seeding.

As to late planting of silage corn, we recollect when, a few years since, owing to the wet June, were not able to get one field planted until July 6th, and by the last of September, when we filled the silo, this lot of corn was almost a full crop, and well eared, though not as mature as they should have been to have gone into the silo. Two years ago we planted an extra piece of Virginia corn after the middle of June, and it attained wonderful size, quite as large as that planted a full month earlier.

***

The remarkable thing the Professor brings out is the excess of protein in the late planted corn, and to find that an acre of Virginia corn planted as late as June 26th, yielded 29 tons of fodder per acre, with 647 pounds of protein in it, is a revalation of itself. As bran is selling here now, the actual protein is about 6 cents a pound, which, if applied to the Professor's corn crop, would make it worth in protein alone fully $39, and more than that it would be possible to sell the husked grain for, from a splendid acre of corn.

All this brings up the protein question: where shall we get it? This experiment explains where part of it may be looked for, but a cow cannot eat 19 tons of silage in six months to get the 450 pounds of protein she ought to have. True, she will get a pound or so in the silage, clover hay, and common feed, generally, but the other pound from where?

I may be a little "sot", but I still think that one of the best ways to get the extra needed protein is to either buy it out direct, or to raise some farm crop and barter it for the needed protein. Oats here are good sale at 34 to 36 cents a bushel, and why not raise the oats and exchange them for "seconds"—fine bran— and make a good swap?

A ton of oats and $2.00 added for grinding, will to-day, here, buy 3,200 pounds of fine bran, containing about 440 pounds of protein, while the ton of oats would have but 184 pounds, or approximately $12 against $26.50, and we have the oat straw left. The oats would have 1,136 pounds of starch to the ton, and the bran 906 pounds, or only 230 pounds difference, worth as carbohydrates in corn maal ¾ of a cent a pound or $1.73, while the gain made by the trade in protein, Ohio prices, would be $14 56.

As gluten meal is selling here now at $16, we put one-fourth of this material, which contains 516 pounds of protein, to the ton, with three-fourths bran, and find it a very fine cow feed. Can I get my needed protein as cheap at present prices, as in raising oats, and with the 45 to 55 bushels per acre, seeding the crop with clover, and exchanging the oats for "seconds" and one-fourth gluten meal? What says Prof. Haecker?

***

I doubt if northern Ohio will ever make a great success with peas and oats as a protein crop. The early summer is usually too dry for field peas, and there is a disposition for the two crops to ripen wide apart. Some years it is all right, and another wrong. Last year the peas ripened long before the oats were fit to cut, and we compromised and made some hay out of them. I found that the clover that followed a crop of oats and peas turned under was a great success, sown about June 1st, right after a good rain, and put down two inches. Cow peas make a great growth, and I think is the great renovating catch crop where clover fails, as it has, to some extent, in this latitude the past winter.

North of here, in Ontario, where it is cooler, peas will grow to be a great crop, but they are not a full measure of success on the south shore of Lake Erie, one year with another. One of our most up-to-date dairymen has tried it several times, and the results are so meager that he has abandoned them, and is building a silo for summer use, and is going to rely upon silage for his extra soiling crop, run in catch crops of cow peas, and the like for this purpose, and buy outright the protein he needs, or exchange home-grown crops of some kind, for bran, gluten and oil meal.

One of the things of dairying, that demands a whole lot of investigating is, that what fits one locality misfits another; as illustrated by the man in Maine, who (page 235) could raise more oats and peas per acre than corn; but in Ohio it would puzzle a man to grow as much roughage in any other form, as in corn.

***

There are rumors in the air to the effect, that a great milk syndicate—nothing smaller can succeed now-a-days—is looking over the dairy fields of Ohio, with the view of locating two, possibly three milk condenseries, and will need next year 5,000,000 cans of milk, size of cans not stated. We are promised revolutions, or something of that sort soon, and events are anxiously awaited. There is no doubt but there is ample milk in northern Ohio to supply all the condenseries that will be erected, but I am not so sure that the northern Ohio patron will take as kindly as he should, to the rules and regulations that he will have to subscribe to to get his milk into the pool at the "greatly advanced prices which will be offered for milk."

Sites for condenseries are being—it is said—looked up at Wooster, Warren, Chagrin Falls, Jefferson, and possibly Wellington and other points. It will be an important addition to Ohio dairying, and as an educational feature, will introduce a care and a concern about the production and handling, not only of the cows, but the milk itself, never known in this state, and in this respect the enterprise should be warmly welcomed.

Whether the parties concerned are eastern or western is not known, but if they locate, build and buy 425,000,000 pounds of milk yearly, and pay eastern prices, it will be an agency to distribute millions of dollars through northern Ohio, and shut up no end of creameries and factories.

Ohio. JOHN GOULD.

Water Content of Butter.

Salt a Factor in the Problem.

ED. HOARD'S DAIRYMAN:—The amount of water in butter is generally supposed to be indicated by the number of drops of water or brine that appear on its surface. Some butter seems to hold a great deal of water in the form of brine which leaks out of the package. Other lots are dry and show scarcely any moisture on the surface or in the wrappings.

This difference in the apparent water content of butter was very strikingly illustrated by that on exhibition at the meeting of the National Association of Creamery Buttermakers held at Sioux Falls, in January, 1899.

One of the features of this convention was the exhibit sent by Dairy Division of the U. S. Department of Agriculture, of some thirty packages of foreign butter. Through the courtesy of Mr. Pearson, who had charge of this foreign butter, the writer was permitted to take a sample from each package. It was while engaged in this work that he noticed the unusual dryness of the foreign butter. There were almost no drops of brine nor any appearance of moisture on the surface of it.

The American Creamery butter, however, was covered with drops of brine. This peculiarity naturally leads to the inference that American butter holds more water than foreign butter, and such opinions have been expressed in various papers.

Chemical analyses have shown, however, that our American butter generally contains a smaller percentage of water than is found in foreign butter. This is illustrated by the following figures:

AVERAGE OF MANY ANALYSES OF BUTTER.

	No. of Analyses.	*Water %.*	*Salt %.*
World's Fair.....	350	11.57	2.78
Wisconsin Creamery	52	12.77	2.87
Danish Butter 1897..	2016	13.79	

These results seem to contradict the impression one gets by seeing the two kinds of butter. The apparent difference in their water content was so striking that on returning from the convention the writer started an investigation at the Dairy School Creamery to discover, if possible, a cause for the dry appearance of the foreign butters.

After two months' work with the assistance of Mr. C. E. Lee, a graduate student in the Dairy Department, a satisfactory explanation of the difference has been obtained.

Without going into any of the details of the work at this time, the final conclusions may be briefly stated. The general outline of the work was to take freshly churned, granular butter, divide it into two equal parts, one of which was salted "one ounce to the pound," and the other was not salted. Both lots were worked the same number of revolutions on a Mason worker, at the same temperature, and samples taken for analysis.

Eighteen such trials were made, and in every case the unsalted butter had the dry, brineless appearance of the foreign butters, while the salted butter showed drops of brine very plainly on its surface.

The chemical analysis showed that the salted butter contained from one to five per cent less water than the unsalted, the average of the eighteen trials being, for the salted butter 11.51% of water, and for the unsalted butter 14 69% water. The salted butter contained an average of 3.24% salt, and as a rule the amount of water decreased as the salt increased, although judging from the appearance of the butter, the reverse seemed to be true.

This experiment explains the dry *appearance* of the foreign butter, since it is a well known fact that such butter contains very little, and in some cases almost no salt.

E. H. FARRINGTON.
Wisconsin Dairy School, Madison, Wis.

Silo Questions.

ED. HOARD'S DAIRYMAN:—In your No. of April 21st, I see a description of stave silo. Notice what is said of using coil wire fencing for hoops. I want to build a silo this summer and have concluded a stave silo would be best. I would like to know the size I should build for 25 cows. I can only build 20 feet high, but can dig out 3 or 4 feet in the ground.

How many hoops of coil spring fencing should this height require, and what amount of silage would this silo hold.

How do you compute capacity of stave silos? The silo described seems to me pretty high. Will send cost of mine when finished. Do you think coat of pitch thinned with coal oil would be good for inside. In our moist climate we have to cover this. C. M. N.

McGhee, Tenn.

In the present issue of the DAIRYMAN you will find a cut showing the manner in which the wire fencing is used for hoops.

A silo 20 feet deep by 17 feet in diameter will hold about 90 tons; enough for 25 cows.

A cubic foot of silage will weigh about 40 pounds.

To find the number of cubic feet in a silo, multiply one half the diameter by itself, and the product by 3.1416, multiply this product by the height of the silo in feet and divide the product by 50. The result will be the capacity of the silo in tons of ensilage.

It is not necessary to paint the silo in any way, but it is probable that a coating of coal tar and gasoline would to some extent keep the wood from rotting and thus prolong the life of the silo.

Queer Cheese.

There is one manufactory in Wyoming County, N. Y., of which but comparatively few of its people have any knowledge. Anyone who is interested in cheese, especially the Italian makes, can post himself regarding one variety of the article, by visiting a little hamlet not 50 miles distant from Rochester or Buffalo on the Erie Railroad. The village is Dale, located in the town of Middlebury, this county, and it is such a little place that it has only a store or two and a postoffice. The cheese factory is not far from the station. It is a small frame building with a receiving door on the first floor. The factory hands are Italians and the farmers who live nearby say the output of the plant is sold in Chicago for Parmesan cheese. The Italians said it was known as something, pronounced like "carzo cawadeller", and from consulting an encyclopedia the writer concluded it was Cacio cavailo, of which there is the Milanno and Sorrento varieties made in Italy. Visitors to the little burgh are shown the establishment as something out of the ordinary. The cheese is made from cows' milk and the farmers about there are paid 70 cents a hundred for milk delivered. The make-up of the plant consists of two boilers, one of which contains hot water and in it the cheese is dipped, after the milk has been turned to curd and is ready for handling, for this cheese is a strictly hand made article. City people, who have seen men in the confectionery store windows pull taffy, know about the way. This cheese in the condition of long curled ropes is placed in a big, low tub and there it is given the hot water baths, between which the Italians pull and re-pull, put back in the tub and then pull it again. The men stand six feet apart and the cheese is stretched at least double that length, until it has reached the proper grain. When it is completed it is shaped into cheeses which resemble a bowling alley pin with the bottom about the size of a cocoanut. It is then aged for about half a year when the outside becomes hard. During the ageing it first becomes green, afterwards a yellow white. The outside then peels off like the skin of a kid glove orange. The article is then said to have cost about fourteen cents a pound. The imported article costs up to 23 cents in New York at wholesale, and is said to be very nutritious. Its sale is said to be larger than that of Gorgonzola, Moliterno, Sirachino di Milano Reggiano, Brescianno di Fasto or Parmiggiano, all of which sell from 20 to 30 cents at wholesale in the United States. An Italian has been at Rock Glen, this country, trying to make arrangements to get the milk of enough cows to start another factory there.

An Oregon Creamery.

ED. HOARD'S DAIRYMAN:—We wish to inform you that after about nine months' persistent effort, a creamery has been organized at Astoria, with capital, building and a proprietor of long experience and well known reputation. This is T. S. Townsend, of Portland, who has several other dairy plants, creameries or cheese factories in Oregon and Washington.

It is the opinion of Mr. Townsend, and, indeed, of all the dairy people who are acquainted with this region, that the coast slope is remarkably adapted to dairying, and that this industry may be carried on here to as good advantage as, or even in some respects, better than, in Iowa or other interior states. At least we mean to try what systematic dairying, by best modern methods will do; and Astoria, being central to the dairy region of both the lower Columbia and of the immediate coast, where there are thousands—or hundreds of thousands—of acres of tide lands and alluvial bottoms, may become a new Elgin.

H. S. LYMAN, Sec. Progressive Association.

Astoria, Oregon.

How Chicks Become Deformed in Incubators.

Complaint is often made about the large number of deformed birds which are obtained when eggs are hatched in incubators. For a long time it was a puzzle to breeders how to account for the fact that the eggs hatched in these otherwise excellent and most convenient appliances produced these crippled chickens; but careful observation has now led to the conclusion that the malformations are principally attributed to the vibration to which the eggs are subjected while the embryo is in course of development. As is well known, the drawers in which the eggs are placed in the incubators have to be opened a couple of times a day in order to admit of the eggs being turned. When looked after by careless attendants these drawers are frequently pushed back with considerable force, with the result that the eggs undergo a severe shaking. It is now found that it is these sudden jerks or jars that are responsible for the deformity of the chickens.

DAIRY MARKETS.

ELGIN, Ill., May 15.—Butter—Firm; offerings 223 tubs; holders refusing bids at 8⅛c on all lots. Official price 18c.

CHICAGO, Ill., May 15.—Butter—Creamery, extra, 18c; firsts, creameries 16½@17c; seconds 13½@14c; dairies, selections 15@16c; extra ladles 12½c; packing stock, fresh 10@10½c.

Eggs—Fresh, at mark, cases included, sold at 11½@11¾c.

Cheese—Full cream Twins, new, good to choice, 9@9¼c; Young America 10¾@11¼c; Swiss 10½@13c; Limburger 7@9c; brick, new, 8@8¼c.

Bran—Quiet, and sold at $10.75 per ton f. o. b.

Cattle—Trade was active, and beef cattle ruled strong to 10c higher. Native cows and heifers ruled firm, and bulls advanced 10@15c. The 200 straight Texas received sold strong at $4.70@4 85 for 1,967@1 233-lb. steers, and $3 80 for 1,295-lb. stags. Best native steers 1,598 lbs. sold at $5.50; top a week ago $5.45, and a year ago $5.15. Most of the native steers sold at $4.80@5.25; corn-fed Westerns $4.50@5.30, and distillery fed steers 1,012@1,274 lbs. $4.60@5. Native cows sold principally at $3.20@4; heifers $4.10@4.60; bulls $3.50 @4.10; stags $4.10@4.80; calves $5@6.75, and feeding cattle $3 85@5.

NEW YORK, May 15.—Butter—Creamery, Western extras 19c; firsts 18@18½c; State extras 18½@19c; firsts 18c.

Cheese—State, full cream, large colored or white, choice, new 9⅝c.

Eggs—State, Pennsylvania and Western, 13¼@14c.

MILWAUKEE, Wis., May 15 —Butter—Creamery, fancy prints, per lb. 17c; extras per lb. 17c; firsts per lb. 15@16c; seconds per lb. 13@14c; imitations per lb. 13@14c; dairy selections per lb. 13@14c; lines per lb. 12@13c; rolls, choice to fresh 9½@10c. Market firm and active; kept well cleared by the trade; receipts 13,355 lbs.

Cheese—American full cream, October Twins 11½@12c; new choice to fancy 9@9½c; Bricks, new, per lb, choice, 8@8½c; Limburger, choice, per lb. 9@9½c; winter made, per lb. 7½@8c; Swiss, Drum, choice, 12½@13c; Block, choice, 10½@11c. New, weak and quiet, with receipts of 7,330 lbs. Considerable inferior new offering which has no quotable value.

Eggs—Fresh, per doz 11c; cases returned. Market unchanged; receipts 733 cases, which are taken by local and storage buyers.

FOND DU LAC, Wis., May 15.—Offerings to-day 354 Twins and 113 Daisies; sales of twins at 8¾c; market steady.

AVOCA, Wis., May 15.—Offerings on to-day's board 609 boxes Twins; market firm; all sales at 8½@8⅝c.

CHILTON, Wis., May 10—The sales reported to-day were 122 cases Young Americas at 9¼c, 123 Daisies at 8¾c and 91 Twins at 8½c.

HORTONVILLE, Wis., May 4—Offerings on board: 194 Twins, 27 Daisies. Sales: 30 Twins at 9c, 50 Twins at 8⅞c. Ruling price, Twins, 8⅞c. Market dull.

BRILLION, Wis., May 5—Sales of cheese on the Brillion dairy board to-day were 109 cases of Young Americas at 9c, 160 Daisies at 9c and 102 Twins at 8½c.

BERLIN, Wis., May 6 There were 203 boxes of Twins offered on the board and sold at 8⅝c. The board adjourned for two weeks to May 20th.

PLYMOUTH, Wis., May 9—There were 480 Twins sold on to-day's board at 8¾c, 50 Young Americas at 9¾c, 20 at 10c and 45 at 10½c.

MANITOWOC, Wis , May 10—The Manitowoc county Dairy Board of Trade held its first meeting of the season to day, with the largest membership in its record. C. W. Sweeting was elected president, this being his fifth term; John Staudt was elected vice-presideut, and Emil Teitgen secretary. Offers to-day were: Fifty boxes Daisies, 40 Twins, 125 Young Americas. All sold. Daisies and Twins at 8½c, Young Americas at 9¾c.

SHEBOYGAN FALLS, Wis , May 10—The sales on the call board to-day were the most active of any sale held here this season. Three hundred and three boxes of cheese were offered, and sold as follows: Two hundred and twenty cases Young Americas, at 11⅓c; 68 Twins at 9c, and 15 Daisies at 9½c. Nine factories were represented.

SHEBOYGAN, Wis., May 10—The sales reported to day were: Three hundred boxes Twins at 8¾c, and 400 cases Young Americas at 10c.

WATERTOWN, N. Y., May 6—Sales 1,204 boxes cheese at 9@9⅛c for large; bulk at 9c; 8⅝c for small and 8⅞c for Twins.

CANTON, N. Y., May 6—Sales to-day: 600 tubs of butter at 16c and 600 boxes cheese, small at 8⅜@8¾c, large, 9⅛@9¼c.

LITTLE FALLS, N. Y., May 8—The sales of cheese: 192 boxes large colored at 9½c; 3,214 small white and colored at 9c.

UTICA, N. Y., May 8—Cheese sales: 40 boxes large white at 9c; 875 boxes colored at 9c; 60 boxes 9⅛c; 254 boxes small colored, 8½c; 25 boxes 8⅝c; 284 boxes, 8¾c; 186 boxes white, 8¾c; 135 boxes, 9c; 893 boxes consigned.

BALTIMORE, Md., May 15—Butter—Market firm; creamery separator extra, 19@20c; extra first, 18@19c; creamery first, 17@18c; creamery imitation extra, 15@16c; ladle extra, 14@15c; western store-packed, 11@13c.

Eggs—Market firm; strictly fresh stock, 12c.

PHILADELPHIA, Pa., May 15—Butter—Solid packed butter, separator creamery, extra, 18½c; creamery firsts, 18c; seconds, 17c; imitation creamery extra, 15c: firsts, 14c; seconds, 13c; ladle-packed, extra, 15c; firsts, 14c; seconds, 13c; print butter, creamery, extra, 20c; firsts, 19c; seconds, 18c.

Eggs—Pennsylvania and near-by, 13½c; western, 13½c; southwestern, 13@13½c; southern, 12½c.

ST. LOUIS, Mo., May 15—Butter—Steady; creamery, 14@17½c; dairy, 12@14c.

Eggs—Steady, 10c.

KANSAS CITY, Mo., May 15—Butter—Steady; creamery, 15c; dairy, 13c.

Eggs—½c higher; fresh, 11c.

CINCINNATI, O., May 15—Butter—Steady; 18c.

Cheese—Steady; good to prime Ohio Flat, 10c.

Eggs—Firm; 11c.

BOSTON, Mass., May 15—Butter—Market firm 18@18½c.

Cheese—Steady, 9@10c.

Eggs—Firm, 13¾@14½c.

WASHINGTON, D. C., May 15—Market firm; extras, 17½c; firsts, 16½c; imitations, 15c.

NEWARK, N. J., May 15—Butter—Fancy creamery, 19c. Receipts liberal.

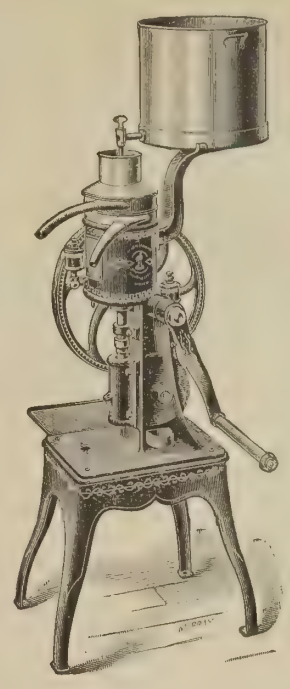
BALTIMORE MARKET.

BALTIMORE, May 11th, 1899—Butter—The receipts of separator creamery from primary points, western and local, have been meager and to eke out this scant supply the wholesale trade have had had to buy supplement parcels from the principal distributing centers, and in getting these in and putting them out, an apparent increase in business is produced which has a beneficial effect upon the tone of the market. Nor has this transient activity been confined to separator goods, for on account of a material shortage in local outputs, both creamery and dairy, trade that has been supplied exclusively from these sources, has been driven to hunt substitutes for them on the street, instead of having it brought to them, or sent to them as usual, and this extra demand has fallen heaviest on gathered cream products and ladles, the natural and regular supplies of which being short also, had to be increased by purchases from points not usually tributary to our market The out-of-town demand has been of more than passing interest, stimulated also by their regular supplies falling short of the normal quantity. There has been an increase in the business done in prints and blocks at fairly satisfactory prices. Receipts of rolls are a trifle freer, and so far there is no improvement in quality; it is a matter of a few days until the passing of rolls, for when the weather settles dry and warm, everything of this grade will have to come solid to insure good prices.

Creamery separator, extras, per pound, 18c; firsts, 17c; seconds, 16c; creamery gathered cream extras, 17c; firsts, 16c; seconds, 15c; creamery, Ohio, extras, 17c; firsts, 16c; seconds, 15c; roll, extras, 14c; firsts, 12@13c; seconds, 10@11c; store-packed, extras, 13c; firsts, 12c; seconds, 10@11c; creamery blocks (2 lb.), extras, 19c; firsts, 18c; seconds, 17c: prints (½ lb.) extras, 21c; firsts, 19c; seconds, 18c; Md., Va. & Penna. prints, extras, 19c; firsts, 17c; seconds, 15@16c.

Cheese—Receipts light; demand fair; market barely steady.

N. Y. State Cheddars, fine, 12@12¼; choice, 11@11½; fair, 9@10; Flats, fine, 12@12½; choice, 11¼@11¾; fatr, 9@9¾; small, fine, 12¼@12¾; choice, 12@12½; fair, 9½@10; Ohio Flats, fine, 11@11¼; choice, 10½@11; fair, 8½@9; Picnic, fine, 11½@12; choice, 10@11; fair, 9¼@10; Swiss cheese, fine, 11@12; choice, 10; fair, 8½@9.



Eggs—Up to the present time the receipts have been liberal, but there has been no accumulation, as the demand has been and is still sufficient to absorb all invoices of choice stock. Our market is in good shape and steady at 12 cents. Attention—As the warm weather is fast approaching, we again urge you to ship your eggs in cases, as they are less liable to become heated and the loss in breakage is much less than in barrels or boxes. So please bear this in mind, especially those who do not understand how to pack eggs properly.

301 Exchange Place. G. M. LAMB & BRO.

NEW YORK MARKET.

NEW YORK, May 13—Butter—Receipts for the week were 35,946 packages; exports for the week, 2,110 packages

"Alpha=De Laval"

CREAM Separators

Save $10.00 Per Cow Per Year.

SEND FOR NEW 1899 CATALOGUE.

The De Laval Separator Company,

WESTERN OFFICES: Randolph & Canal Sts., CHICAGO.

GENERAL OFFICES: 74 Cortlandt Street, NEW YORK.

BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

It has been a good butter market, buyers well up on the bit, receipts of finest creamery just about enough to go around, and prices firm, closing at 18c; and winding up here Saturday night with clean floors.

The scarcity of extra creamery created a better demand for all good to fine grades and sales were freely made at 16@17c. Fine dairy butter sold at 16½@17c, while inferior quality was neglected and offered at 14@15c. Some little inquiry for imitation and ladle goods for export: some sales reported at 13@14c. We quote:

Creameries, extra, 18c; medium, 17@17½c; poor, 15@16c. Dairies, extra, 16½@17c; medium, 15@16c; poor, 13@14c.

Cheese—Receipts for the week were 16,269 boxes; exports for the week were 1,873 boxes.

Better market here and in the interior and prices are advanced ½c on the week's business. Very light stock here and prices are firm at the close. We quote:

Full cream, extra, 9½@9¾c; medium, 9@9½c; poor, 6@8c; part skimmed, extra, 8@8½c, medium, 6@7c; poor, 4@5c; old cheese, extra, 9@9½c; poor, 5@7c.

Eggs—Receipts for the week were 91,315 packages. There is a good demand for fresh stock and prices are a trifle higher. We quote:

New York & Pennsylvania, per dozen, 14½@15c; western, 13¾@14½c; southern, 12@13½c.

177-179 Chambers St. DAVID W. LEWIS & CO.

Latest quotations for fancy creamery—New Orleans, 17½; Buffalo, 17½; St. Paul, 17; Minneapolis, 16@17.

FOREIGN MARKET.

BOSTON, May 13, 1899—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane, give butter markets as again low in price, but the demand is good. The low prices have stimulated consumption greatly, nothing but low grades of American left, which is selling from 15c downwards for ladles. Some fresh Canadian creamery, in boxes just landed, brought 19@19½c. The weather continues rather favorable to the make, and Denmak is sending rather large quantities. The home and Irish make will now increase greatly, and prices for all grades of butter must tend downwards for some little while yet.

Cheese markets are all quiet, with prices tending downwards. Buyers continue a very conservative policy, taking only sufficient for pressing and immediate wants; this requires holders to shade values. New cheese is freely offered from America and Canada with prices receding.

LIVERPOOL, May 15—Butter—Finest United States, nominal; good, 65s.

Cheese—American finest white, 51s; colored, 50s; ordinary new, 49s.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—"Reta's Parole," 20 months' old, solid color, and standard bred. Fine individual and well behaved. Direct blood of best St. Lamberts and Combination. F. L. GASTON, Normal, Ill. 12-tf

For Sale—Fifteen h. p. boiler and 15 h. p. upright high speed engine nearly new, also 6 h. p. engine. GEO. WOODRUFF, Adm'r, Janesville, Wis. 14-4

Wanted to purchase—Good second-hand Cream Separator. Give make, capacity, price and how long in use Address A. S. COEN 708 Deleware St., Kansas City, Mo.

Position wanted as manager or foreman of stock farm. 33 years of age, with good recommendations Experience in the business. Address with particulars, H. A. N., care Hoard's Dairyman.

For Sale—Russell Pasteurizer, 50 gal. capacity. PASTEUR MILK LABORATORY, Washington, D. C.

Wanted—Position at once as manager or working foreman of good dairy farm. Thoroughly understands dairying and farm management in all its branches, such as erecting and starting plants, handling all kinds of farm machinery, and especially fitted for caring for thoroughbred stock. First-class butter making a specialty. Address G. P. KNAPP, Clinton Corners, New York. 14-2

For Sale—Short-horn bull calf by Earl of Irvin No. 125805; dam, Countess Flora. Beautiful light roan, dropped Jan. 5, 1899. Price, $60.00 f. o. b. here. HENRY LACY, Syracuse, N. Y. 14-2

For Sale—"Brown Bessie Omaha" Bulls. A great combination. GEO. E. BRYANT, Madison, Wis. 13-2

Wanted—Farm superintendent on dairy farm in Waupaca County. Fine house and pleasant social surroundings. Permanent position on salary. Married man, with experience. Good references required. M. C. PHILLIPS, Oshkosh, Wis. 13-4

Tamworths, ready to wean, $10 each, or $15 delivered. Hermanville Farm, P. E. I., Canada. 32-52

For Sale—Five Holstein-Friesian Bulls ten and twe ve months old. Also B. Plymouth Rock eggs for hatching. Address C. W. SCHERMERHORN, Charles City, Iowa. 11-4

Wanted—Man and wife on a farm. Man to do ordinary farm work and woman to cook and do housework. Apply to A. KENNEDY, Supt., Indian Ford, Wis. 13-2

$75.00 will buy registered bull Gerben Mechthilde Sir Josephine 2d, H. F. H. B., born August 28, 1897. Reason for selling, compelled to give up dairying. C. KAHLER, Prairie du Chien, Wis. 11-4

Wanted—A first-class man to rent a fine dairy and stock farm within three miles of the city of Janesville, Wis. H. F. KELLER, 251 South Jackson St. Janesville, Wis. 12-4

Half Rates to Madison, Wis., via the North-Western Line. Excursion tickets will be sold at one fare for the round trip from stations in Wisconsin and Michigan, for trains arriving Madison the afternoon and evening of May 25, on May 26 and for trains arriving Madison before 1:30 p. m., May 27, limited to include May 29, account of Inter-Scholastic Meet, etc. Apply to agents Chicago & North-Western R'y. 13-2

Exceptionally Low Rates to Sioux Falls, S. D., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, May 26 and 27, limited to include May 29, account of meeting United Commercial Travelers of America. Apply to agents Chicago & North-Western R'y. 13-2

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, XIV.

CONTROL OF INFECTIOUS DISEASES.

Agriculture has been greatly benefitted by the discoveries made in recent years, in the realm of veterinary bacteriology. A knowledge of the cause of many of these contagious maladies has been of inestimable value, as it has led to a much more thorough understanding of the nature of these diseases. So long as the cause of disease was unknown, so long was rational treatment difficult, and prevention almost impossible.

It is too common a belief, even now, that diseases of this class, as well as any other, are attributable to something that the animal has eaten or to some change in climatic conditions. It is more natural to look upon these as causal factors than to conceive of the cause as a living germ too small to be recognized by the unaided eye. The majority of communicable diseases are produced by the ravages of vegetable parasites, the bacteria. In a few cases already known, fungi (molds and related species) function as the cause of disease, as in the lumpy jaw, and a number of the skin diseases. Then again, the phenomena of parasitism often occurs in the animal kingdom. In the preceding paper, reference has been made to Texas fever, and also to malaria in man, diseases which are caused by animal parasites of the lowest order, which attack the blood corpuscles, while among the worms and insects, there are numerous species that have adapted themselves to a life in other forms.

While the invading parasite, be it a bacterium, fungus, or any other form, is absolutely essential to the production of any specific disease, still it requires more than the mere presence of the parasite in question to produce the disease. The other factor which is just as necessary is a susceptible host for the invading parasite to affect.

Unless the specific germ finds its way into such a host, disease will not occur. An animal may possess such natural powers of resistance as to be naturally immune. In such a case, even though a virulent disease germ found its way into the body, no disease would result. This would be the case with the virus of hog cholera in a horse. On the other hand, the immunity or resistance that an animal naturally possesses is frequently overcome by the operation of various factors, some of which are dependent upon the animal itself, and others on the surroundings. Temporary debility, occasioned in a multitude of ways, may predispose the animal to disease. Over exertion, close confinement, over feeding, especially where a one-sided ration is used, and poor ventilation of stables are also factors that may render the system much more susceptible to the inroads of contagious disease. The age of the animal often plays an important role. In black leg the young stock are much more susceptible, while in tuberculosis the percentage of cases increases with the age.

HABITS OF DISEASE BACTERIA.

In attempting to fight animal diseases, it will be of value to remember that disease cannot be caused unless the specific organism is present. Disease germs, as a rule, are not universally distributed throughout nature. In some cases, as in lock jaw or tuberculosis, the distribution is much wider than it is in others, but for the most part, even in these cases, the causal organism is generally found in more or less close proximity to existing or preceding cases of the same disease. Thus, the tubercle bacillus is much more abundant in the dust of a stable occupied by tuberculous cows, or in a house occupied by affected people. This is most strikingly illustrated in the case of the tenement houses in New York city. Many of these buildings are veritable incubators of this disease. From one to four or even more cases appear in many of them, year after year, with almost unvarying regularity.

MODES OF DISTRIBUTION.

Unwittingly, disease is often introduced into our flocks and herds. One of the most frequent causes is in the purchase of stock that has the disease in an unrecognized form. With tuberculosis, this is by far the most common mode of introduction. This is particularly true with reference to this disease, because it develops so insiduously, and its presence is not generally recognized, until the secondary stages are reached. In hog cholera or swine plague, the same method frequently serves to spread contagion. In these cases, contact with the diseased animal, or its discharges, is sufficient to start infection. Animals may also come in contact with diseased animals on other farms through the pernicious habit of exchanging sires or dams for breeding purposes.

Another method whereby disease is frequently disseminated is through the medium of the drinking water, where animals have access to streams and ponds that receive the drainage from other farms. In diseases of swine, also in anthrax and black leg, this method of distribution is by no means uncommon. Practically all of the disease bacteria are able to exist or grow in water, so they are readily distributed in this way.

Again, indirect communication is also frequently established by numerous other agencies. Of most importance aside from those already mentioned, is man himself, who through carelessness often serves to bring destruction on his own flocks. Living animals of all sorts, dogs, birds and different vermin, contribute to a greater or less extent.

One channel, the influence of which is greatly exaggerated in the minds of most people, is that of the air. Many of the different disease germs are able to withstand drying for considerable periods, but under natural conditions they are not usually spread for any great distance in this way. Even with a germ that is as resistant as tuberculosis, it is hardly probable that other animals acquire it, under field conditions, except in occasional instances, unless by direct contact with each other. Where animals are closely confined, especially if stables are imperfectly ventilated, the conditions are much severer.

A knowledge of the ways along which disease is spread often forearms the stockman and enables him to avoid trouble, a course that is infinitely cheaper and more satisfactory, although it is difficult to make him see this until he has passed through an outbreak of some infectious disease.

PREVENTION OF DISEASE.

To some extent, it is possible to test an animal for certain diseases, and so determine their condition before others are exposed. The tuberculin test in tuberculosis, the mallein test in glanders, represent this type. It goes without saying that the use of these aids is commendatory in purchasing animals more especially where the owner is sure that his other stock is entirely free from the specific disease.

Where no specific test exists, it is advisable to practice the method that has been of so much service in the limitation of human disease—quarantine. The old idea of quarantine expressed in the very derivation of the word (quaranta giorni; the Italian for forty days) indicated an iron-clad separation for a given period, which was practically the same, regardless of the character of the disease.

Modern bacteriology has largely relieved quarantine of its vigors, because it attempts to apply the proper period of isolation for each respective disease. In some cases, a short detention suffices to determine the fact whether the animal is diseased or not.

While the importance of preventive measures is recognized in the abstract, only a very limited number of individuals take such precautions as would enable them to keep their flocks and herds free from disease. Their especial interest is not awakened in the subject, so long as their herds are doing well, but let an outbreak occur, and the importance of these preventive and restrictive measures appears more concrete. But under such conditions, they are interested more in a "cure". They want immediate relief, something which will save their herds. While this is the condition of the man whose flocks are infected, yet his neighbors need at this time more than at any other, the counsel that looks to prevention, to the avoidance of an outbreak, rather than the healing of one after it has broken out.

CURING DISEASE.

The very nature of most of communicable diseases is such that but little hope is offered of a cure. Where the disease germ has established itself in the animal body and has passed through the necessary period of incubation, generally the trouble is so well seated that a positive cure is often out of the question. Whether the affected animal lives or dies will depend more frequently upon the constitution of the animal than upon any other factor. Our agricultural and veterinary papers are full of reputed "cures" for different diseases of this class, but the great majority are merely nostrums, designed to catch the unwary. In a few cases, as in the iodide of potassium treatment in lumpy jaw, real efficiency has been secured, but this is exceptional. The extensive studies that have been made of late years on the causation and treatment of disease have yielded wonderful results but for the most part success has been more marked in preventive rather than curative medicine. Most of these methods rest upon the principle that disease may be warded off by increasing the immunizing power of the body. This method reaches its fullest value in the anti-toxin treatment for diphtheria in the human species. This refractory condition of the body maybe reached by the introduction of an immunizing substance as in the anti-toxins, or it may be caused by the injection of the living germ of the disease, modified and weakened in its virulence by artificial cultivation, until it is no longer able to produce fatal results.

The use of this latter method has been of great service in such diseases as anthrax, black leg, and hydrophobia, as they generally permit of the saving of the portion of the herd that has not yet succumbed to the disease. In the case of hydrophobia, the remedy is even efficacious after the animal has been bitten and the virus introduced.

This is because the incubation of the disease is so slow that the antidote can overcome the effect of the virus before it has developed sufficiently strong to show physical symptoms of the disease. The present indications strongly point to the development of a similar treatment in the case of hog cholera, but the method has not been tried sufficiently long to warrant definite conclusions as yet.

The Stone Silo.

Ed. Hoard's Dairyman:—On page 107, of the Dairyman, H. P. asks "which keeps silage best, stone or wood?"

I have used a stone silo seventeen years—that is, the lower eighteen feet of the silo is stone and the twelve feet above is stone on the two outside walls, and wood on the two inside walls.

The lower nine feet is in the earth below the feeding floor—in one corner of a stone structure 40x50—the balance of the lower story stables thirty-four cows. It is hardly necessary to say that the walls were well built, for they are seemingly as perfect as when built forty-two years ago.

For a few years, the silage rotted about six inches next the wall, which I attributed to the conducting character of the stone walls. I then lined the walls with ship-lap lumber. I would say rather imperfectly, as the air got in at the cracks and the silage rotted worse than before. I then took out this wood lining, plastered the walls smooth with cement, and I have not had any rotting of silage since.

With this experience, and a pretty thorough study of this subject, I have not the least doubt that what is required for a silo wall is, to be strong, air tight, and smooth, with no overhanging projections or concave spots. If I had stables built for fifty cows

TESTED BY THE MILK PAIL

Quaker Dairy Feed

is made entirely of grain—principally of oats—combined in scientific proportions. It is complete for the production of milk and the proper maintenance of the animal.

Sold only in sealed and branded sacks.

An Economy. The careful proportioning of fat and carbohydrates to protein and the balancing of feeding stuffs and feed to the needs of the animal is economical in the greatest degree, and renders the choice of Quaker Dairy Feed a necessity. It makes milk, and no ration is complete without it. Send for

in every household. It is clean, tasteless and odorless—air, water and acid proof. Get a pound cake of it with a list of its many uses from your druggist or grocer. Sold everywhere. Made by STANDARD OIL CO.

Parted In A Dream—(New) Pronounced by critics a beautiful song. Very popular. Founded on strange incident of Cuban war. Regular price, 50c. Sent to our readers for 25 cts., post-paid, including also miniature page of Darling Lenore and Mother's Darling Yet.

Darling Lenore—(New) Is called a very catchy, pretty song with beautiful flowing melody, all in waltz time. Becoming very popular. Regular price 50 cts. Sent post-paid to our readers for 25 cts. with a miniature page of Parted In A Dream and Mother's Darling Yet.

Mother's Darling Yet—(New) Pronouuced very pretty. Is extremely popular with singers of lullaby songs. Regular price 50 cts. Sent post-paid for 25 cts., and with it a miniature page of Parted In A Dream and Darling Lenore.

For 2 cts. I will send one miniature page of each of the three songs. Address the author,

HALBERT L. HOARD, Fort Atkinson, Wis.

and wished to provide them with forty pounds each of silage a day, and was to build a silo outside the stable, as near the stable as possible, I would make it round, say twenty-four feet in diameter, ten feet in the ground, walled with stone or brick and plastered smooth.

Above the walls I should stud it with 2 x 4 lumber, twelve feet high, more or less. I should paper the inside of the studs and then cover with ship-lap lumber as tightly as possible. I have no doubt that good, dressed ship-lap about three-fourths of an inch thick will bend to the studding and make a strong, durable job, and, if covered on the outside in a similar manner, durability would be assured.

Such a silo would be much stronger than the stave silo, and even cheaper than a stave silo, two or three inches thick. I should up end a stick in the center of the silo. It may be a round one from the woods made smooth, or an eight-inch square one with lumber spiked on the four sides, with a groove or slot on each of the four corners an inch wide, which is designed to hold one end of a partition. The other end of the partition is to be held by a similar groove made of two pieces of lumber about ten inches wide, attached to the side of the silo wall, making four apartments to the silo; as the partition boards are placed in position as the silo is being filled.

Inch lumber will be strong enough, if the silage is filled in regularly on all sides of the partitions at the same time. The central post and the side posts cut off the sharp angles at the three corners of each apartment. It will be well to put in the partitions as the silo is filled, which will give an opportunity to mix the silage more evenly.

Such a silo, if properly filled, would contain about 190 tons of perfect ensilage, and the top exposure of the silo, while feeding out, would be equal to that of a silo eighty feet high—no fear of stale silage for the whole year.

Such a silo eleven feet in the ground and nine feet above, surrounded by a lean-to sixteen feet wide, will give ample room for forty-four cows, headed to the center and plenty of space for manger and feeding alley between their heads and the silo.

Now, if we continue this lean-to or structure up sixteen feet more alongside of a friendly bank, preferably on the northwestern side, in such a manner that we could floor from the top story entrance to top of silo—this would admit of the silo being four feet higher; also admit of the ensilage cutter being on a strong table four feet higher, or on a level with the load of ensilage to be cut, and no carrier or elevator required, which is the most troublesome of the machinery used.

In addition to this, I would get sufficient sheet iron to go twice around the top of the silo, turn the ends so as to hook together, making a temporary hopper. When one width was filled, I would add another width on top. This when well filled, I would adjourn the filling for a search for stone, from fifty to about one hundred pounds each in weight, to the amount of about twenty tons, and place on the silage to weight it.

I assume that if the silo was properly filled, that the stone would settle down some four feet and could be taken off and piled away for another campaign. I am aware that weighting is voted unnecessary—can't be put on a thirty foot silo at reasonable cost. But that does not prove that weighting won't pay, both in quality of ensilage and silage room or storage.

I consider that silage room is well worth 50 cents a ton a year, to any farmer that has stock to feed ensilage to.

This last planned silo at 24 feet deep, would hold about 204 tons without weighting, and if weighted as I have described it would hold about 252 tons—48 tons more than the same silo space not weighted, which at 50 cents a ton would be $24. This at a cost of the labor in putting on and taking off the stone, some three dollars.

Objections have been made to the getting out the ensilage from below the feeding floor. I have found that it is less labor to get the ensilage from my lower nine feet of the silo, which is below the feeding floor, than it is to get it from the upper nine feet

The work of feeding ensilage from such a silo is about equally divided between two men, one in the silo to fill the baskets and hand them out to the other who feeds them. Pitching out and down from above, and repitching is more labor than the plan I proposed.

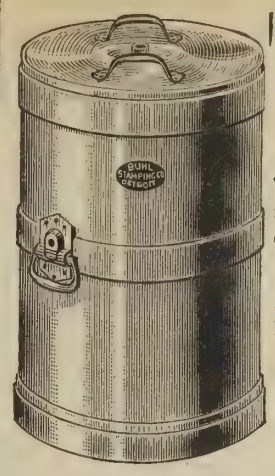
The first seven or eight feet below the feeding floor is handed out very easily. With the aid of a short step-ladder a few more feet can be handed out with little more labor. One great object to keep in view is having the silage as near the stock as possible.

Rocky Run, Wis. UNCLE FRED.

Curing Sore Teats.

ED. HOARD'S DAIRYMAN:—In your issue of March 24, Subscriber, Kerrmoor, Pa., wishes to know how to cure teat on young cow. I am no veterinary, but have had forty years experience with dairy cows.

The first symptoms of a closed teat is scattering of the milk; you rub your finger over the end of the teat and you will find there a glutinous substance. On discovering this, take a small dish with kerosene oil about one-half inch deep in it, and everytime for a week, after a milking, soak the teat for about three minutes in it. I have never failed to cure a case when I started as soon as I saw the first symptoms of it.



If the teat has got bad, do not pick the scab from the end; take warm water and castile soap and soak it off gently. Picking irritates the teat and makes it sore. It takes a little time, but a man can afford a little time for a good cow, and no man who reads HOARD'S DAIRYMAN one year will keep anything but a good cow any longer than he is obliged to. J. E. ROWELL.

Middlesex Co., Mass.

WHAT IT IS WORTH.

Mr. B. J. Stahlman, of Eddy, N. M., in renewing his subscription says:

Your paper is easily worth $1. of any dairyman's money, if he will just read it and try to profit by its teachings. Then when I get my index at the close of the volume and bind the numbers together, which I always do, I would not take $3.00 for it, for it is one of my most valuable reference books on anything in the dairy line; so you see I get $4.00 in value for $1.00 invested or 400 per cent. It is not every day we can do as well with our money.

BUHL CHEESE FACTORY CANS

Excel in Strength, Finish and Durability.

They will not leak or rust, are easy to clean, and keep the milk fresh and pure. The body sheets are the finest imported Cookley K Tinned Steel.

CAPACITY : 15, 20, 30, 40 and 50 Gallons.

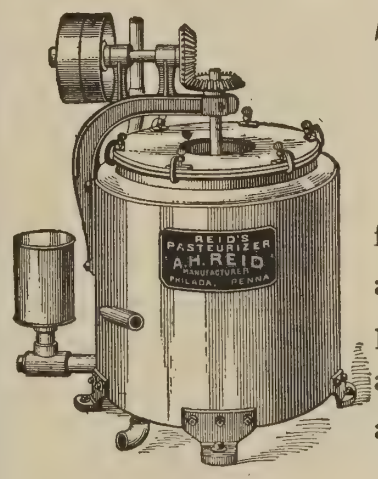
DEERING POPULARITY

YOU CAN'T KEEP IT IN.



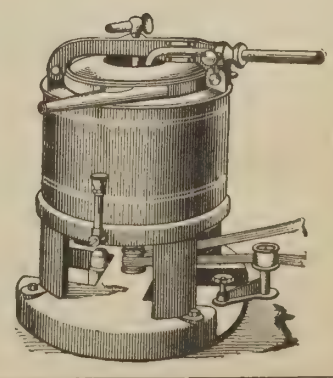
An old proverb says: "He receives most favors who knows how to return them." This is the secret of the great popularity of **Deering** grain and grass cutting machinery. The confidence placed in them by the farmers of the world is never *mis*-placed.

Deering Binders, Reapers, Mowers, Rakes and Corn Harvesters

return the favor of popularity by steady, reliable, satisfactory work in the harvest. Deering made the first successful application of ball and roller bearings to harvesting machinery, and the decided advantage in lightness of draft held by **Deering** machines today (over all other makes) shows conclusively that there is one *right* way of doing it—and that there are several *wrong* ways.

The **Deering** way is the common sense way.

DEERING HARVESTER CO., - - CHICAGO.



They All Admit It.

Even the strongest opponents of pasteurization are forced to admit these facts; it kills all germs, and removes all garlic and odors or taints in the milk; pasteurized cream produces a more uniform quality of butter, under varying atmospheric conditions and makes the butter keep longer and retain its flavor better.

Whether you sell your cream or make it into butter, get a

REID Pasteurizer.

It will prove to you conclusively that pasteurization PAYS. The best machine for skimming either hot or cold milk is the **Reid Latest Improved Long Spindle Separator.** Catalogue and complete information mailed free.

* Adding one fifth to test.

Onwa has a weekly butter test of 18 lbs. 13½ ozs.; sire, Diploma, son of Combination, dam, Oneida 2nd. Thus it will be seen that Onwa is inbred to a certain extent. The enclosed yields will give the readers of your valuable paper the result of such breeding. It seems to me that this article would not be complete without the yield of Oneida 42100. She has a weekly butter test of 16 lbs. 13 ozs. and has given us in the last two years 23,141 lbs. 10 oz. milk, that yielded 1,211 lbs 9 oz. butter. Her average Babcock test was 4.43 per cent fat, and her average daily grain ration was 14 lbs. JAMES E. DODGE.

Hood Farm.

The Soja Bean as a Substitute for Clover.

ED. HOARD'S DAIRYMAN:—In your issue of April 14 I note an inquiry by T. A. W., of Mo., in regard to cow peas for winter dairy feed. Having had some experience, with them, I will report what I know about peas.

A few years ago, after scoring my fifth consecutive failure on clover, I gave it up and turned to cow peas. They did not fail, but, Oh my! the memory of their harvesting makes my back ache now after four years' rest.

The vines grew from twelve to fifteen feet long. They were waist high, all in a tangle, rotted next to the ground, and when cut with a mower it took two men and a boy to part the swath before I could cut another swath.

I could have rolled up the cut swath like rag carpet for two hundred yards in a strip without a break in it.

They were so matted and lodged that it was impossible to cut them clean. Some vines, after the swath was torn apart, showed three or four feet of uncut vine straightening up towards the sun. The vines would not cure evenly. The leaves on top parched and shattered off while the vines were still green and wet underneath. There were only a few seeds on them. The soil was quite rich.

On thin soil they are somewhat more prolific and do not run to vines so badly. Horses and cattle ate them fairly well after they got used to them and I considered them a good forage crop, but not good for hay as they take too much work to cure and if a soaking rain comes, they are almost sure to rot enmasse, for it is next to impossible to tear them apart and dry them out as you can clover.

The next year I tried the medium early soy and soja beans and will not bother with either clover or cow peas any more. Instead of waiting fourteen to sixteen months for a more than uncertain clover crop, I can grow as much and better feed in four months' time. Instead of having to cut the crop inside of a week, wet or dry, to get it at its best, I can have six weeks time to suit the weather and my convenience in which to cut.

Instead of a long sprawling, matted, rotting mass of vines, I have an upright growing plant holding its leaves and stem up out of the dirt, with large pulpy leaves which cure much quicker and more thoroughly than the cow peas. They can be cut at any time for feeding, either green for soiling or for hay from the time they bloom till ready to ripen for a seed crop.

Alfalfa is a very uncertain crop here in Illinois and of little or no value the first year for either pasture or hay, and only grows on porous clay loam. Cow peas are good crop to grow to plow under, or pasture off, but if you try to grow them for hay you will be disappointed.

Clover yields no grain crop for feeding purposes. Cow peas on very rich soil run to vines with few seeds. On thin soil they yield better, but make less forage and hay.

Soja beans thrive on any soil. They will grow where it is too poor to grow clover, and unlike cow peas will yield all the more both of hay and seed on rich soil.

With us in central Illinois, cow peas will yield seed, 10 to 20 bushels per acre, soja beans 10 to 60 bushels. Cow peas will tear the "inards" out of a threshing machine with their long tough vines, but sojas thresh easily.

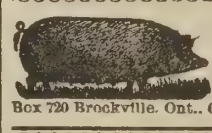
As to the comparative value of the three crops, according to the Government bulletins, clover contains when cut green, 4.4 per cent of protein or nitrogen condensed into food; cow peas contain 2.2 per cent; soja beans 4 per cent. Of fat or carbohydrates, clover has 1.1 per cent; cow peas 0.4 per cent; soja beans 1.0 per cent. If made into hay they contain respectively 12, 16, and 15 per cent protein but if the seeds are allowed to mature on the vines, they add to the latter in their composition as follows: Cow peas, protein 20 per cent; fat 1.4 per cent. Soja bean seeds add 3.4 per cent of protein and 17 per cent of fat.

Soja seeds are two per cent richer in protein than oil cake meal, 20 per cent richer than wheat and oats, and 24 per cent richer than corn. Of fat the sojas contain 17 per cent, linseed oil cake meal 3 to 7 per cent, corn 5 per cent, bran and middlings 4 per cent.

When siloed with green corn, the sojas make a perfect balanced ration. For calves and pigs, the beans, either green or dry, make the best possible feed, to produce health, bone and muscle.

In protein or fat they are a rich condensed food, far superior, in fact, to any of the high-priced mill products, and one you can grow anywhere and on any soil. If fed judiciously there is no danger in feeding them to any stock as a hay crop, but the seeds are too rich to feed horses; they are too loosening, owing to the fat in them.

Both the cow peas and soja beans can be sowed broadcast or with a grain drill for a hay crop, but for a seed crop it is better to plant in drills, 20 to 30 inches apart, and 10 to 15 inches apart in the row. A drill corn planter does the work nicely, and they require but little cultivation. A half bushel to one bushel will sow an acre for a hay crop, and for seed in drills ¼ bushel is enough.



Either crop will add to the fertility of the soil where grown, enough to pay a good rental. When they become known and rightly appreciated, they will become for the farmer and dairyman as much a standard crop as corn or oats. W. H. S.

Macoupin Co., Ill.

In Favor of Oleo.

ED. HOARD'S DAIRYMAN:—Much has been said and written against the manufacture and sale of butterine, and in favor of the anti oleo bill, which is to be pushed in next Congress. Now, if admissible, a word or two might be said on the other side of this question, which might have the effect of provoking discussion, which might set some right, who may have a wrong opinion.

If we are rightly informed, the proposed bill increases the tax on oleo 10 cents per pound, and prohibits the use of coloring, which will practically suppress the business.

Pure Bred **Tamworth Pigs**, Bacon curers choice. Pure Bred **Ayrshire Cattle**, largest imported herd in America. Stock all ages for sale. R. G. STRACY. Box 720 Brockville. Ont., Canada.

Into Your Herd.

SIRES IN SERVICE:—The prize winning IDA'S RIOTER OF ST. LAMBERT 10th, the champion CATONO KHEDIVE, the champion CZAR COOMASSIE, and IMP. GOLDEN BAR, inbred through his sire, Aristocrat, and his dam, imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey.
Write for what you want. Visitors always welcome. JOHN E. ROBBINS, Greensburg, Ind.

Now the writer questions very seriously the justice of such a measure. There are thousands in limited circumstances, who prefer to use butterine at 15 or 18 cents per pound, than to do without butter of any kind, because they are not able to pay 25, 30 or 35 cents per pound. It may be claimed that they can obtain butter at this time of low prices, for less money; this is admitted, but what they get is butter in name only, at least half the time, with coloring added.

I am acquainted with a host of families which use butterine, not because they are compelled to for want of means, but simply because they can procure a better article than they can get in buying so called butter as sold in our markets.

We know from personal observation, and have also heard the statement made over and over again by consumers, that butterine is preferable for table use to the average country butter found on our markets, outside of creamery and the so-called guilt edged articles. Now if the butterine manufacturer can make a better article at less money, why not let the people have the benefit of it?

Mr. Editor, is it not time to give the overworked farmer's wife a rest? She has been trying these years to make the butter of the country, at a disadvantage, and this drudgery has told on her both mentally and physically.

Now if we have mechanical and chemical and what not processes, that give us a better article for the same price, or less, it would seem to be the thing to have. Let the farmer produce the fats required in the manufacture of oleo and butterine, and get his income with less worry and work, and his wife and daughter have more time for mental culture and social enjoyment.

This bill prohibits the coloring of butterine, but allows the careless, slovenly butter maker, which, alas is too often found on our farms, to bring her greasy compound with variagated smells to market, with all the coloring she has a mind to use, in order to deceive the buyer. I ask, would not the passing of this bill be a clear case of class legislation?

If this fight is between the creamery and oleo people, which seems probable, I would say, let them fight it out; or if the consumers of these products have a grievance, claiming they are imposed upon or defrauded, let them fight the battle; but as long as we as farmers are sure of the job of furnishing the material for either process, and as a rule opposed to class legislation, can we not afford to stand aloof?

If you see fit to publish this squib, it will be a target that will no doubt draw fire from some one, and as fire is purifying, it might be just the thing we want to clear up our ideas on this subject. FAIR PLAY.

Ohio.

The law does not prohibit the manufacture of oleo, nor does it tax uncolored oleo. The proposition is to tax colored oleo so that it shall not be sold as butter to those customers who prefer the product of the cow. Those who wish to buy the compound of paraffine, cotton seed oil and animal fats, which is sold as oleo, can still continue to do so, but the tax will prevent its being colored in imitation of fine creamery butter, and sold at a large profit, to those who may have an old-fashioned prejudice in favor of butter, and against paraffine, as an article of diet.

Cedar Hill Dairy Notes.

Dairy House Construction.—Butter and Cream Notes.

ED. HOARD'S DAIRYMAN:—Since my last communication we have been more than busy at Cedar Hill, arranging our farm work, building creamery, hen houses, etc. Our creamery now has three rooms, and all rooms are bricked between studding and plastered, making cool rooms in summer and warm in winter. Our room for refrigerator, butter worker and printer, is so built that morning is the only time during day when the sun can strike it.

Our separator, churn and cream vat are in a room 14×16. Boiler is in a room by itself, so that the heat from it does not affect creamery proper. We have our boiler bricked in, which is a saving of fuel.

We secured a plum in our cream vat. The vat was especially built to exhibit at last winter's state dairy meeting, held at Galesburg. It is a natural wood vat with a liberal ice-box on end. Speaking of cream vats and cream, reminds me that hot weather is soon to be with us again and soft butter will be the reward of those who do not do the act properly.

I find that we have a solid, fine grained butter in the hottest weather by following this method: Run cream over aerator, full of ice-water, cooling down to 50 or 55° F., then put in vat and use plenty of ice; hold in vat within 24 hours of churning, then warm up to 70 and put in a liberal starter. Do this in morning, in evening stir well and again add ice, so cream will be at 55 or 58° F. until next morning, when it will be churned.

This method can be used in daily churning by adding starter in the morning and ice at night. The cream cooled for 12 hours will always make a better grained butter than if cooled just before churning.

We have in our stables 32 Jerseys in milk; 7 of them are two years old, with first calves; 9 cows are only strippers. Yesterday our two days' cream churned out 60½ pounds of butter, and since then the herd has gained 29 pounds of milk, which is the result of turning cows on grass at night as well as during the day.

Yesterday we ordered cotton seed meal and think it is the first that ever came to Warren County as a feed for milch cows.

Monday we will have a 200 egg incubator full of Plymouth Rock eggs, come off, and Tuesday one of 200 eggs of Single Comb Brown Leghorn chicks. Will report later.

"BUFF JERSEY."

An Increased Production of Butter in Australia Looked For.

ED. HOARD'S DAIRYMAN:—It is well known that Australia's butter industry, which showed such rapid development at the start, has been checked the last three years by severe drouths in the dairy districts. Had it not been for these drouths it would not have been unreasonable to have looked for last year's exports amounting to 750,000 boxes.

It must be borne in mind that the production of butter, to be sold in England at even 16c or 18c a pound, is about as profitable business as farmers in Australia and New Zealand can be engaged in. This assertion has been made by some of the best posted people in the dairy interest in these two colonies of Great Britain.

The increase in the number of dairymen has been constantly going on, and had this not been so the shipments from these two colonies, to Great Britain, would have fallen off much more than they did, in consequence of these drouths having been so severe. It not only killed off a great many, but lessened the producing condition of cows greatly.

As anything that may have a bearing on the output of butter from the antipodes, an extract of a letter from parties who are largely engaged in the exporting of butter from Australia, may be of interest to those engaged in the butter industry in this country.

Under the date of Melbourne, March 23, 1899, these gentlemen write me as follows: "Now, as regards this colony, we have had wonderfully good autumn rains, which mean first-class natural feed throughout the country during the autumn and winter; in fact, these rains are the best we have had in this colony for some years. During the last three or four years we have had warmish summers and no autumn rains, resulting in the cattle coming into the autumn and winter in rather poor condition, and there being no feed, through the want of rain, they simply existed; in a great many instances they starved; and this means they came into the spring without heart and in a miserable condition, besides there being a considerable shortage from mortality.

This season it looks altogether different; we have had a very good spring and summer, the latter being exceptionally cool, though during February we had a spell of warmish weather, but the weather is now again cool, and we have had the rains before mentioned, and we therefore look very hopefully towards next season, as there will be an increase in the dairy stock and they will come into the next season in thoroughly good condition, so we expect the production will show a considerable increase on the past four seasons.

The exports to Great Britain are in the neighborhood of 320,000 boxes of 56 pounds each, this season."

Boston. GEO. A. COCHRANE.

Packing Butter in Brine.

ED. HOARD'S DAIRYMAN:—A subscriber from Florida complains in a recent issue of the DAIRYMAN that in spite of all precautions and scrupulous cleanliness, etc., the butter will get strong in a few days.

Dairy literature of the present day is replete with sugges tions as to the importance of cleanliness, proper ripening of the cream, purity of the salt used, about scalding and exposing to the sun all utensils used in the dairy and so on; but very little has so far been said about how to prevent butter from being contaminated by the germs in the water that is used to wash out the butter milk, which are able to undo all other precautionary measures.

The Danes, who rejoice in an international reputation as the banner butter makers of the world, use only water that has been sterilized (boiled), knowing that even the clear, cool water, from the deep well, is just as apt to be impure as any other.

Boil the water the day before the butter is to be made; if salt is used boil it along with it, cover and set away in a cold place. Strain it before using; provide brine as strong as salt will melt (also boiled), strain into jar considerably larger than would hold the quantity of butter that is to be preserved; drop i nto the brine, see that the brine surrounds the butter at bottom, sides and top. Something heavy to keep the butter all under brine, must be placed on top so that it cannot turn lopside; otherwise the butter will swim on top.

It is surprising how long butter will keep sweet if protected in this way. Yes, cheese can be made profitably from one cow's milk, if a good curing room is available; a sweet curd cheese would be most convenient as it takes less time to make it and is a better keeper and can be held until opportunity is favorable to sell.

Sometime hereafter, will give receipt for cheese making that is suitable for a small quantity of milk. M. SCHEMBRI.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

Mr. Wheaton's Canadian Dairy Notes.

Spring Dairying.—Canadian Dairy Exports.—Prices of Dairy Products.—The Dairy Outlook.—Cheese Curing Rooms.

ED. HOARD'S DAIRYMAN:—On May 1st began a new season in connection with the dairy industry of this country. After the close of the factories in the fall it takes till the end of April of the following spring to dispose of all the product.

The disposal of this very product has been done very effectually this spring. On May 1st there was little if any old cheese held on this side of the Atlantic, and what there was was held on English account.

The total exports of cheese from Montreal, for the past season from May 1st, 1898 to May 1st, 1899 amounted to 2,374,414 boxes as against 2,603,084 boxes for the previous season, showing the large deficit of 228,670 boxes. The exports for the same period from New York were 407,879 boxes, as compared with 735,944 boxes for the year previous, showing a decrease of 328,065 boxes, and making the total decrease from Canada and the United States 522,431 boxes. The total value of the Canadian cheese exports was about $15,500,000.

Turning to butter we find a more satisfactory showing, in so far as Canadian butter exports are concerned. The total exports of butter from Montreal from May 1st, 1898 to May 1st, 1899 were 370,225 packages as compared with 265,912 packages for the previous season, an increase of 104,313 packages. The total exports from New York for the same period were 152,206 packages against 201,827 packages, being a decrease of 49,621 packages and making a total increase from the two countries of 54,692 packages.

During the season, prices for dairy products were very well maintained, especially the latter part of the season.

At the beginning of the season prices for cheese were low and contined so until well on through the summer when the great falling off in the make caused the market to advance considerably. But as is often the case, the factorymen did not get the full benefit of the rise as most of the fall cheese was in the middlemen's hands, before the highest prices prevailed. This fact however was not altogether a misfortune to factorymen as they are likely to reap the effects of it in better prices for the new season's make.

Prices for creamery butter at the close of the season were about the same as they were at the beginning, namely: from 16½ to 16¾ cents at the factories. Higher prices, however, prevailed during the greater portion of the season, the winter creameries realizing from 19 cents to 20 cents for nearly all their out-put. This fact, when the increased exports are considered, must be very gratifying to those interested in the development of an export butter trade.

It may be well just here to look forward a little and see what is in store for our dairymen in connection with the season upon which we have just entered. Our cheese trade has reached such proportions that a decrease in exports occassionally is really a blessing in disguise. We have frequently pointed out that this trade has about reached its limit in so far as quantity is concerned. Consequently in any year when there is an unusually large make, as was the case in 1897, low prices are sure to prevail. And so it is, that the large deficit of the past season has served to restore prices to a good paying price, and to make the prospects for this season better than they have been for the past year or two. A year ago, old cheese was selling at from 8½ to 9 cents, while to-day it is quoted 11c. Last year at this time, fodder cheese sold at 8 to 8½ cents at Montreal. While this year it is worth from 9½ to 9¾ cents. Of course this better price will cause a largely increased make which may overstock the market and bring with it low prices again.

On the surface the outlook for butter does not appear so bright as that for cheese, yet our creamerymen have nothing to be discouraged in regard to it. Dairymen, when they compare the price of butter with that of cheese this spring consider the former low in price; whereas it is just as high as it was a year ago and with the prospects for a big season's trade, brighter than they were a year ago at this time. Activity in exporting circles is beginning earlier and with the enhanced reputation which Canadian butter got through last season's trade, we may look forward to a very large increase in that trade during the present season.

Last season the value of our butter exports was considerably over $4,000,000, thus making the total value of our exports of dairy products fully $20,000,000, no small amount to come into a country like this for distribution among the 180,000 persons directly interested in this great dairy industry.

Curing rooms and curing cheese continue to be interesting topics in dairy circles on this side. Considerable has been said and written in regard to these, but too much advice cannot be given so long as it is good and sound, and thoroughly practical. As a rule, it takes years of preaching and teaching, where so many different factors are concerned, to obtain anything like perfection. And so our advice to those who are engaged in this good work is, never to let up till every curing room is properly fitted up for curing the cheese, as it should be cured; and not only that, but never stop this good work till every factory has proper and efficient sanitary arrangements.

A somewhat new interest has been created in this subject of curing rooms, by a recent action of the local government for the Province of Quebec. This action is nothing more than the offer of a premium of from $100 to $200, as to the size of the curing room, to each factory in that Province that will fit up its curing room according to instructions furnished by the Department of Agriculture, so as to control the temperature and moisture and cure the cheese properly.

While many may not favor bonusing industries in this way, they cannot help but admire the determination and zeal displayed by those in authority in our sister province, in their efforts to improve the quality of their dairy output.

This premium offer should not only be an incentive to the dairymen of Quebec to put their factories in order, but should stimulate those in other provinces, and especially in Ontario, where no such inducement is given to do likewise, lest they lose the place they now occupy as the banner producing section of the Dominion.

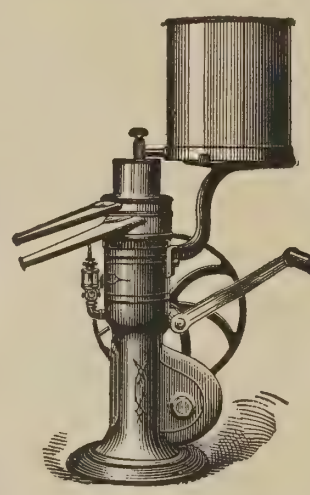
The instructions given and the conditions laid down by the Quebec authorities, upon compliance with which a premium may be secured, are such, that if fully carried out, cannot help but result in great improvement in the quality of cheese made in that Province. These conditions are divided into four groups; those relating to the construction of the factory, and to the curing room in particular; those relating to the ventilation, cooling and heating of these rooms; those which concern the general laying out of the factory, and those relating to the manufacture and other questions.

In the construction of the curing room, special attention is given to the walls. Over the double outer-lining of boards, two layers of felt paper are laid, and over the paper double clap-boarding. Over the double inner lining of rough boards there is to be one layer of paper; on the paper, strips two inches wide and one inch deep. On these a double thickness of one inch rough boards and on these two layers of felt paper, finishing up with a double thickness of planed boards. This mode of construction will be required on the inner walls, separating the curing from the working room, and the floor must be such that it will not sag or sink.

Proper ventilation must be provided, and cylinders for putting ice in to keep the temperature down in the hot weather, must be put in. (We have not space here to describe fully these ice cylinders, but may do so later on.) Where possible, the curing room must be heated by steam pipes fed from the boiler. For controlling the humidity in dry weather, there should be a steam pipe with a small valve which may be slightly opened when needed.

Respecting the construction of the factory, generally it should be built on high ground where the drainage is good. The working room should be well ventilated, and in no case must the whey vat be placed under the factory. In short, the plant must be sufficiently good to permit of the manufacture of first-class cheese before any bonus can be secured.

The conditions respecting manufacture,



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co 's Color has the highest standing in the markets. . . .

ZERO
CREAMERY

Uses either water or ice. Does its work perfectly. Possesses desirable features found in no other. Efficient, inexpensive, clean, low temperature.

Water alone will do the work. Money saved.

The Most Complete Creamery and Refrigerator on the Market

ZERO CREAMERY CO., PERU, IND.

etc., are worth quoting in full, and are as follows:

1. That the factory should, if possible, belong to a syndicate, if there be one in the region where it is situated. If there be none the person in charge of the factory shall submit to its being inspected whenever the Government requires.

2. It shall bind itself not to ship any cheese which has been less than a fortnight in the curing room.

3. The manufacturer shall bind himself to wash out the whey vat every day. (We wonder how many makers elsewhere would like to undertake such a task.)

4. He shall keep a record of the temperature on blank forms to be supplied them by the Department of Agriculture.

5. The water used shall be as pure as possible.

From this necessarily condensed resumé of the conditions laid down for receiving this bonus, it will be seen that, if the factories largely take advantage of the offer and obey the instructions given, the province of Quebec will be placed in the very front rank in so far as well equipped and properly made factories and curing rooms are concerned.

Toronto, Canada. J. W. WHEATON.

Concerning the Healthfulness of Silage as a Food for Cows.

ED HOARD'S DAIRYMAN:—G. E. H., Hamilton, Ont., writes: "Our local board of health contemplates condemning silage as a food for dairy cows. I am interested, having built silos for farmers."

It hardly seems possible that boards of health in these days can seriously consider such action as is here reported. Of course there is such a thing as bad silage, and where such is used the milk produced from it should be condemned, but silage as a food for dairy cows should not come under the ban of any board of health simply because it is silage. The prejudice against silage still lingers and works to its detriment in some cases.

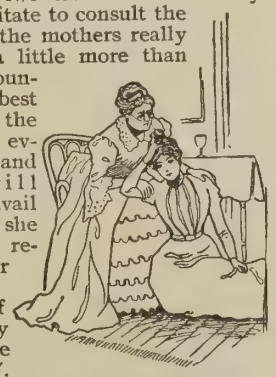
For example, it is often quoted that the milk condensing factories will have nothing to do with milk produced from silage-fed cows. Probably this prejudice arose in the early times when very green, immature corn was converted into silage with a sour, unsatisfactory product resulting. That the milk condensing factories are hardly warranted as a class in taking the position they do at the present time, is nicely brought out by the experience of the factory at Lansing, Mich., which I have reported in "Feeds and Feeding." The story runs that the factory people were greatly pleased with the milk received from a certain patron, both because of the large quantity turned in and its satisfactory character. After noting with satisfaction the product of this party, the managers of the factory were surprised to learn one day, that for some time past he had been feeding silage. At first they were disposed to be excited over this finding, but wisely reasoned that as they had been praising this particular milk they could hardly now raise objections to it, because of the discovery that silage was being fed. Like good business men they allowed their prejudice and preconceived notions to melt away, and raised the question whether or not it would not be a good thing for the factory if more farmers fed silage. As a consequence of further investigations, the Michigan Milk Condensing Co. prepared a pamphlet of nearly one hundred pages, telling how to build silos, how to fill them, and how to feed the silage.

This pamphlet was distributed gratuitously among the patrons of the condensing factory, who were urged to build silos and feed silage. At present quite a portion of the milk received at this factory is from silage fed cows, and the experience covers a sufficient number of years to preclude all possibilities of error in regard to the wisdom of recommendations for silage feeding, made a few years since.

It is a fact that silage is fed upon many of the best dairy farms in America, both where milk is produced for direct consumption in the cities, and for cream trade as well as for butter and cheese. A couple of years since the writer found silage extensively used at Governor Morton's farm at Rhinecliffe, N. Y. A ton of milk a day was being shipped to New York City and sold at fancy prices.

A visit to the Havermeyer farm, Mahwah, N. J., revealed the same situation. At the Twombley farm, (Mr. Twombley is a son-in-law of W. K. Vanderbilt) Mr. Hope, the dairy manager, was using silage. Mr. C. I. Hood, the noted Jersey breeder at Lowell, Mass., was found using silage.

A notable instance is that of Mr. Francisco, at Fairfield, N. J. Mr. Francisco started in the milk business in the humblest manner. His first effort was in carrying by hand from house to house, milk produced by one cow and her two heifers. From this small beginning his dairy interests advanced until at the time of my visit he was selling milk of 180 cows, and that was the smallest number milked at any time during the year, for it was the summer season, and a goodly portion of his patrons were away from home at the seashore. Mr. Francisco's trade is in the Oranges and Newark, N. J. His great stables and beautiful spring house are all kept scrupulously clean and neat. While on my visit of inspection, several visitors called at the office and pleaded with the manager to furnish them milk, saying they were willing to pay any price for milk that had the reputation his had. At the stables, silage fed the day of my visit, which was in August, and I was told that it was given to the cows every day throughout the year.



Now, how can such things as these be if silage is really the poor feed which some claim? A rich man's name, or the advertisements of some firm, may induce people to try their goods, but no one will use milk or other dairy products long, which are really poor in quality, simply because they are well advertised, or have some great or wealthy man's name behind them. People would not long use milk from Governor Morton's farm, or from Mr. Francisco's great dairy if it were really of low quality.

W. A. HENRY.
Wisconsin Agricultural Experiment Station.

THE secretary of the National Butter Makers' Association has issued the report of the seventh annual meeting, at Sioux Falls. We are requested to state that only those members who are in good standing will receive a copy. Butter makers and others, who send $1.00 to the secretary, at Elgin, Illinois, will receive a membership card and report.

If all young women could have the right sort of motherly advice much of the unhappiness of the world would be avoided.

There are two troubles in the way. The girls hesitate to consult the mothers and the mothers really know only a little more than the girls. Counsel of the best sort is at the command of every woman and if she will promptly avail herself of it she will soon be relieved of her troubles. Thousands of women, every year, write to Dr. R. V. Pierce telling their symptoms and asking his advice, which is freely given without cost.

For over thirty years Dr. Pierce has been and is to-day chief consulting physician of the great Invalids' Hotel and Surgical Institute, at Buffalo, N. Y. He is a specialist in the diseases of women and his "Favorite Prescription" has had the greatest sale of all medicines ever devised for the cure of the troubles peculiarly feminine.

Every letter addressed to Dr. Pierce is held sacredly confidential and has the most careful attention.

No testimonial letter is ever published until the written consent of its author has been given.

Mrs. Mary E. Lewis, of Tanner, Gilmer Co., W. Va., writes: "For fifteen years I suffered untold misery. I had given up all hope of ever getting well. I could not lie down to sleep, and everything I ate would almost cramp me to death. Was very nervous and could hardly walk across the room. I only weighed ninety pounds when I commenced taking these medicines; I now weigh one hundred and forty pounds and am having better health than ever before. I have taken the 'Favorite Prescription,' the 'Golden Medical Discovery,' and the 'Pellets.' I take great pleasure in recommending your medicines to the sick for I know that if it had not been for them I would not have been living to-day. I am very thankful to God, who put the great power in your medicines that cured me."

Gentlemen

The Gluten Feed finally got here. It arrived here the 16th, was glad to get it for our cows were failing in their milk every day. They have gained in the last four days to twenty five gallons more per day than they were while we was out of the Gluten Feed.

We think Gluten Feed is second to none as a milk producing feed, it makes more milk and better milk than any other feed we can get.

Yours Respectfully
John Shugart & Son.

Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating "Value of Butter Fat in Milk," all FREE if you address

Ohio Prohibits Coal Tar in Food.

The great dairy state of Ohio says that coal tar is dangerous as a food product. Coal tar is the base of much of the butter-color now on the market, and butter in which it has been used is declared by law to be unfit for food. If you wish to know whether the butter you are eating is colored with coal tar, send to us for the material for making the test and we will mail it to you free of cost together with directions for its use.

Thatcher's Orange Butter Color

Is a pure, healthful vegetable color, free from deleterious substance. It gives butter the delightful June tint. For sample bottle send to

THATCHER MANUFACTURING CO., - Potsdam, N. Y.

We illustrate above one of Shipman Bradt & Co.'s very convenient arrangements for carrying bottled milk in their low down, short turn dairy wagons which you will find advertised on cover page of this paper. This is a new departure in dairy wagons and is in line with the advanced ideas of the leading dairymen of the country. The plan of delivering milk in bottles is rapidly growing in favor with both the dairymen and their customers, and this illustration of a thorougly convenient system, economical of space, built right into and a part of the wagon, has been brought to our notice. All of the crates with the exception of the lower one in front, slide back and forth, giving the driver easy access to all bottles from his seat near the center of the wagon. The crates are removable and can be taken out and filled in the milk room. The front and rear are both completely enclosed and thus protected from the outside atmosphere. Where it is desired to carry ice, these two compartments are lined with galvanized iron, leaving an air space between the iron and the outside of the wagon, thus making it practically equal to a refrigerator.

The wagons built by this firm are especially adapted to carrying bottled milk for the following reasons, viz.: the body of the wagon is rectangular, there being no jogs or offsets, thus giving unbroken space inside of the wagon for your crating, and, in fact, much more room inside for the same size and weight of body than the wagons with a jog in the box. The body of the wagon hangs low—only twenty inches from the ground—hence your load (although the wagon is crated nearly to the top) rides much steadier and better than in a higher wagon. The wagon is just as low at the rear as it is at the sides, which makes it easier and more convenient to load the most of your milk from behind.

We believe that this firm has what many of our progressive dairymen are looking for and we bespeak for them a great success in this new departure. You can get a complete description of all of their different systems for handling bottled milk by addressing, Shipman, Bradt & Co., DeKalb, Ills.

Our Special Elgin Letter

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade aggregated 13,380 pounds. Bidding opened at 17 cents and advanced to 18½ cents, but manufacturers refused to sell. Bidders were not eager to pay more, and the call closed with no sales made. The Quotation Committee announced the market steady at 18 cents.

The sales for the corresponding week of the three preceding years were as follows:

May 16, '98, 17,460 lbs. of butter sold at 15 cts.
May 17, '97, 15,960 lbs of butter sold at 13⅝ cts.
May 18, '96, 37,920 lbs. of butter sold at 15½ cts.

The New York market was reported firm at 19 cents. H. C. B.

Elgin, Ill., May 15, '99.

Cultivation of Vetches.

ED. HOARD'S DAIRYMAN:—I see in the DAIRYMAN of April 21st, J. P. D. asked about vetches. I presume he sowed his vetches in the spring; they must be sown in the fall, one and a half bushels to the acre. We prefer them, in Oregon, to the Canada pea. They will yield twice as much feed and of a better quality. Sow on dry ground in October and you can cut two crops.

They are said to be fine for ensilage. Try them. W. M. POWERS.

Oregon.

ED. HOARD'S DAIRYMAN:—In answer to J. P. D., in April 21st DAIRYMAN, with regard to growing vetches, I will say that from three years' experience in growing them in a small way, that they must be sown very early. Have sown them in February, May and September.

Those sown in May were not worth cutting; those sown in September made from 2½ to four tons hay per acre.

There are several varieties. The common vetch or tare (Vicia sativa) is the one I prefer. The sand vetch, or winter vetch (Vicia villosa) is very slender when young, growing slowly at first. It is probably somewhat hardier. Last September I sowed 12 acres, mostly vicia sativa.

From February 1st to 6th, we had the coldest spell, but one, ever known in Oregon, west of Cascades. I sow wheat with the vetch to suppprt the vines. Winter killed at least three fourths of the wheat and about two thirds of the vetches, so I think that it is at least as hardy as wheat.

I used to live in Minnesota and would not expect much of it there as winter wheat does not usually stand the climate. It might do sown as early as possible in the spring.

Some time ago the DAIRYMAN made me a ration formula with vetch hay and a desire was expressed that I report as to the effect of feeding it in the amounts indicated, viz: 17 pounds daily.

I have seen no bad effects from feeding it in a small way, and Prof. Jas. Whitcombe, Vice-Director of Oregon Experiment Station, and formerly state veterinarian, says that it is one of the best forage crops grown here and that it can be fed in any quantity (the hay) without bad results. He prefers the common vetch (Vicia sativa), it being more palatable. H. W. DOWNING.

Yamhill Co., Or.

A Quintet of Questions from Nebraska.

ED. HOARD'S DAIRYMAN:—If cow sticking belongs to the sorry past, what is the cure for bloat?

2. Is it profitable to feed cows grain on good pasture? If so, what, with corn 15 to 25 cents, shorts $10 and bran $8?

3. For winter feeding with alfalfa, will it pay to grind corn at a cost of 8 cents per hundred pounds when hogs follow cows?

4. With above feed, what is a ration for a Jersey bull with alfalfa? With bottom prairie hay?

5. Do we get a fair test by sending milk to a separating station, after standing in cans over night? If not, what can be done?

I am a new subscriber and a new dairyman. Can see how one might fail with, but cannot see how one could succeed without HOARD'S DAIRYMAN. D. C. B.

Culbertson, Neb.

1. The best cure for bloat is to prevent it. This may be "easier said than done," but nevertheless, there are precautions which will certainly reduce the liability to bloat, even on green alfalfa. First of all, do not turn the cows with an empty stomach into an alfalfa pasture. Give them, at least, a half feed of dry forage before turning them out, and then not let them stay out too long. Next, provide some stack or pile of dry forage to which they can have free access while in the pasture.

If after this, there should come cases of bloat that do not yield readily to the minor remedies which have been suggested in the DAIRYMAN from time to time, we should not hesitate to resort to the trocar—a sharp pointed, three-cornered instrument, enclosed for two-thirds or more of its length in a sheath, called a canula, much used for inserting rings in the noses of bulls, and a most convenient instrument for many purposes. Before using it in a case of bloat, it should be immersed in boiling water, or otherwise be perfectly sterilized. Leave the canula in the opening until all the gas has escaped.

2. We advocate little or no grain on good pasture at close range. But such pasture is usually of short duration. Corn and cob meal makes a very satisfactory addition to pasture grass. Unground corn on the cob would do very well, if not too dry and hard. In that case it might be a good deal softened by soaking for twenty-four hours or longer—a much cheaper practice than paying 8 cents for grinding.

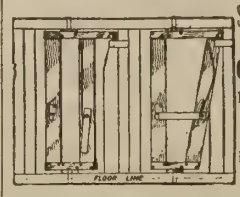
3. This question is sufficiently answered above.

4. A bull having plenty of good alfalfa hay will require little or no grain. A "nubbin" of corn now and then ought to suffice. With wild hay, we should depend almost exclusively upon bran, with perhaps a slight admixture of shorts, if his condition seemed to require it.

5. The accuracy of the test will depend altogether upon the representative character of the sample, and this in turn upon the thoroughness with which the cream is re-incorporated with the milk, by stirring and pouring and then taking the sample without any delay.

Cheap Production of Milk.

Lively discussions sometimes have been aroused in farmers' meetings, by someone making the statement that rich feed does not increase the richness of a cow's milk. This assertion, although it is not of so much importance to the dairyman, as is the question of producing milk cheaply, always arouses considerable opposition. No argument is necessary, however, to convince a dairyman that he ought to think on the question of reducing, to its lowest terms, the cost of producing a quart of milk, but nearly every one who has milked cows for a living, will take exceptions to the statement that he cannot feed fat into milk. This and some questions, like the cause of low prices, are talked about a great deal, without much effect. Economical milk production is, however, the supreme question for a dairyman to consider, and his time is much more profitably spent in studying this problem, than in making complaint about making market prices. Like most everything else, that is bought and sold, the price of butter is influenced by the supply and demand. If each one of us should stop to consider that this is a large country, and that the annual butter crop is estimated to be 1,400,000,000 pounds, he would soon realize what a contract he is undertaking, in attempting, single-handed, to change the market price of butter. As milk producers or cow owners, our time is about the same as wasted, if it is spent in wrangling over financial problems. The milk or butter which every dairyman offers for sale, ought to be a quality to bring the top market prices, or he should know the reason why. It does not cost any more to produce pure milk than dirty milk, in so far as the cow is concerned, but as the question now under discussion, is how to reduce the cost of milk, rather than how to improve its quality, we will not digress at this point. Numberless illustrations can be cited to show how wealth has been accumulated by saving a fraction of a cent a pound, in many manufacturing processes. In creameries the amount charged patrons a pound for making the butter, has been considerably reduced since they began operations, about fifteen years ago; but what has the cow owner done during this time to reduce the cost of producing a pound of milk? Many have given the question a great deal of thought, and if they have been successful in increasing the profit from their cows, by decreasing the cost of production, you will find that one important factor in their success has been liberal feeding. When we come to realize that 60% of all that a cow can eat is required to keep her alive, and that a holding back of any part of the remaining 40% is increasing the cost of what she does produce, then the cows will be fed all they can safely eat. This is well understood by men who feed cows profitably. One way in which they reduce the cost of production to a minimum is by giving the cows plenty of feed.



If a certain quantity of food will keep two cows alive and nothing more, for a year, the same amount given to one cow during the same time will not only support her, but cause her to give enough more than the two cows gave to pay for the feed and help toward supporting the milker. Scant feeding increases the cost of the milk a cow produces, just as a small fire under a boiler may make the water warm, but unless it is sufficiently hot to generate steam, the wheels will not go round and the fuel is wasted. After each cow owner has demonstrated to his own satisfaction, and in his own way, that liberal feeding is profitable and scant feeding expensive, he should begin to consider what kind of feed pays him best. As the corn crop is pre-eminent in this locality, the dairyman should devote a good share of his thought to considering the most economical method of converting it into milk. It has been shown by experiments (Feeds and Feeding, p 251) "that corn fodder yields about twice the dry matter that can be secured from a crop of roots on the same land."

These observations, however, indicate that roots and hay supply only about one-half as much food per acre as corn, and demonstrate the superior feeding value of corn. There has always been a difference of opinion, however, as to the best way of feeding the corn crop to the dairy cows. Some advocate cutting, shocking and curing the corn in the field, while others preserve in silos. The construction and continual use of the silos by so many prosperous dairymen, it seems to me, is convincing evidence of the economical value of ensilage as a milk-producing food.

This fact in itself should at least lead cow owners to consider the advisibility of trying this on their own farms. In addition to the fact many prosperous dairymen continue to use their silos, a great many experiments have been made with ensilage at our agricultural colleges. These show—Feeds and Feeding, p. 349—that the losses of material are about the same when corn fodder is cured in the field in the shocks as when it is preserved in a good silo; "that the digestibility of the corn silage and of dry fodder is practically the same," and that in actual feeding trial with dairy cows, ensilage "gives better results than a corresponding amount of dry fodder." In one experiment the silage ration produced 11 per cent more milk than was obtained from the dry fodder ration and in another the difference in favor of silage was 5% in milk and 6% in butter fat. Many similar illustrations of the economical value of ensilage can probably be given by those who have fed it to dairy cows, but the repetition of such data will not necessarily strengthed the fact. Ensilage can be counted on as an economical feed nearly every year, but selection of the cheapest grain feed for milk production is quite another question. The fluctuation in prices from year to year is such that each season and locality must be considered by itself when it comes to selecting the kind of grain that should be fed to cows in order to make the most milk at the least cost.—E. H. FARRINGTON, University of Wisconsin, Madison, Wis.

REDUCE YOUR COAL BILL
BY USING
The No Scale Company's
High Grade Boiler Compound.
Trial orders solicited. No charge unless satisfactory. Write us. M. D. Watson Gen'l Agt, 551 Marquette Building, Chicago.

$48.50 FOR THIS $80.00
TOP BUGGY. Wheels and Gear made of second growth air seasoned hickory, tough as whale-bone, double reach, iron full length, improved 5th wheel, with King Bolt in rear of axle, will never break. Springs, highest grade oil tempered steel. Forgings all made of Norway iron. Trimmings all wool 16 oz. imported English broadcloth, finest produced. Springs in back and seat cushion. Seat ends padded. Painted under the 100 day system. All parts first dipped in hot oil and allowed to stand until perfectly dry, giving foundation for paint. Best Oil, Lead & Varnish used.
NO MONEY We will ship this elegant Top Buggy or any Phaeton, Surrey, Trap, Wagons, Carts, or Harness shown in our 164-page catalogue subject to examination, if not found satisfactory, return it at our expense.
FOR FIVE YEARS We will give with each one of our Special $48.50 Buggies a 5 years binding guarantee. We have no agents, we deal on a strictly cash basis, have no losses, therefore, in buying of us you do not pay any agent's profit, or any one elses bad bills, because we never have any. Send for our FREE 164-page catalogue.
Marvin Smith Co. 18 B-D, 55-57-59 N. Jefferson St. Chicago

A Wise Dairywoman.

It is seldom that we have run across a plainer, more compact and intelligent statement of sound dairy experience than the following, written by a woman for the *National Stockman and Farmer*. It would be a grand thing for the future wealth and well being of the country if a large proportion of the dairy farms and dairy cattle were in the hands of just such women:

About ten years ago we took a basket of butter to our county seat. Although we received the top price they were paying for butter that day, we were not satisfied, and thought we had better look up a city market. A friend gave us the address of a firm in one of the most noted cities in the United States. The following week we sent a box of butter to the above mentioned city, not knowing anything about said firm. We waited eagerly for the returns, and when we received them we were greatly pleased, for we got ten cents per pound more than we did the previous week at our home town. We are to-day shipping to the same city and the same firm. In all these years we have never fallen short an ounce in our weights. Several times there were two-pound blocks taken on the road. After that we had the express agent put the railroad seal on each box, and the butter has never been molested since.

We are not obliged to send any given amount each week, we send what we have. We may send ten pounds less this week than we did last, or perhaps send twenty pounds more, and it is all right. We ship once a week. The butter is never over a week old when it reaches the market. We receive our pay once a month.

After we had shipped butter to the above firm one year we wrote to the manager and asked him what he thought of our butter. His answer was, "If you improve as much in the next year as you did this you will be making first class butter." Now we did not get angry and say, "He'll not get another pound of butter from us, for he don't know what good butter is," as some would have done, but the next week we sent him a nice note thanking him for being so frank with us, and asked him in what points we lacked. His answer was this, "Your butter is not colored highly enough and is a little overworked. For our trade it should be the color of grass butter in June, and also about twelve per cent water. When breaking a roll, little sparkles of water should be seen between the granules." These few words were a great lesson in butter making to us. In a few months he wrote us again the following words: "You need not make any changes in your butter. I have customers for all of your butter just as it is, and wish you could send us two hundred pounds more a week."

There are many such markets open to farmers if they would only look them up and stay by them until they could establish a trade. The first essential in butter making is an even color the year round, second the same flavor the year round, third the same shaped roll, with the same prints on each week, and salted the same each time you churn, put up in parchment paper in a neat form.

True we are not all born butter makers, but we can all read up and take advice from others. We received more good practical advice from the late A. L. Crosby on dairying in *The Stockman and Farmer* than we did from any other source, as his writings were all practical. We have all the old papers filed away and they make interesting reading connected with our experience.

It is a lamentable fact that there are so many butter makers that do not try to improve and say, "It don't pay to spend much time fooling with the stuff, for we don't get much for it." Such women don't know that the more time they waste on the butter the less value the butter will be. Butter never ought to be worked more than once. The sooner the butter is taken out of the air the better it will be.

Several years ago a good substantial firm of Cleveland sent out one hundred letters to farmers for country butter, as they were in need of country rolls. A great number of farmers sent them butter. In conversation with the manager a short time ago he said; "We could use only a few farmers' makes, as the color of the butter was all shades, never twice the same color, and all the different flavors that could be gathered in a roll of butter, were present in some of the makes." And the butter wrappers were also of a peculiar make. Some of them had buttons on with the button holes torn out, and it could easily be guessed what they were originally made for. H. L. G.

Food Adulteration.

The testimony given by Prof. A. S. Mitchell, before the Pure Food Commission in Chicago, is of great interest to dairymen, as showing to what extent adulteration of food has taken possession of the country. Part of the testimony was as follows:

Some of the facts brought out by Senator Mason's pure food inquiry at the Grand Pacific hotel yesterday, were these:

That a commodity for sale throughout the United States, and in popular use among dairymen and milkmen for the preservation of milk and cream, and by bakers for the preservation of cream puffs, chocolate eclaires and similar pastry, is a product of wood alcohol, which is absolutely poisonous; that this preparation is used by undertakers for the preservation of dead bodies and by health authorities for the disinfection of buildings where virulent diseases have been treated.

That ground tarred rope has been used to adulterate ginger.

That absolutely pure flour is a rare commodity; that it is adulterated with ground stone and clay from Tennessee and Georgia.

That pure buckwheat flour is rarely to be purchased after it passes through the hands of a jobber or a wholesaler, that one barrel of pure buckwheat flour is generally mixed with two barrels of inferior spring wheat flour, that can be purchased for less than one-third the price of the buckwheat.

That nearly all powdered sugar is composed in great part of corn starch.

That nearly all black pepper is adulterated with what is known as "buckwheat shorts" (hulls).

That retail butter dealers in the city daily violate the oleomargarine law.

That flavors sold at sodawater fountains as the juice of strawberries, bananas and pineapples, are chemical compounds.

That pure vanilla extract for flavoring purposes is almost unknown, and that the flavorings for such extracts as are sold in the market, are in the main derived from cumarin; that lemon and other flavoring extracts are also adulterated to a very great extent.

SHOWS A SAMPLE OF "FREEZINE."

A. S Mitchell, Chemist of the Wisconsin Dairy and Food Commission and the Wisconsin State Board of Health, was the expert witness who testified as to the use of the poisonous preservative by milkmen, dairymen and bakers. He produced a sample bottle that was labeled with the trade name of "Freezine." The label bore the name of B. Heller & Co., Chemists, 249 to 253 Jefferson St., Chicago. Samples of other preservatives, which Mr. Mitchell declared to be poisonous, were produced in evidence. Senator Mason sent Sergeant-at-Arms Hutchinson to summon the officers of the Heller Company to appear before the committee this morning.

Mr. Mitchell testified that the cream of tartar ordinarily sold by grocers, consisted mainly of phosphate of lime and alum mixed with starch. He went extensively into the question of the adulteration of wheat flour and buckwheat flour, the use of cocoanut shells and peanut shells in food products, and confirmed the testimony with reference to the adulteration of coffee with "Black Jack"—the inferior bean shipped here from Germany and Brazil. And at this point in the testimony Senator Mason remarked: "We'll introduce a bill that will stop the Germans from sending any more of that stuff here."

PARAFFINE IN LARD.

Lard, said Mr. Mitchell, is adulterated with cottonseed oil, which has the effect of softening the lard to such an extent that it is necessary to use paraffine to restore its consistency. Paraffine is a product of petroleum and is absolutely indigestible.

C. Y. Knight, secretary of the National and Illinois Dairy association, produced four packages, purchased by himself and said to contain creamery butter. As a matter of fact, he had been supplied with oleomargarine, for which he had paid 18 to 20 cents a pound. The first package had nowhere about it any mark indicating the nature of the contents. Another package had the word "oleomargarine" faintly stamped on brown paper on the inside. Each of the other packages was stamped in a corner of the brown paper wrapper, so turned down that no purchaser would notice the stamp until careful search for it.

Augustin Gallagher, former revenue agent for the enforcement of the pure-food law, told of the adulteration of flour with ground stone and clay and other deleterious substances. The pure flour law, he said, had been beneficial, and, in large measure to the operation of that law he attributed an increase of 20 per cent in the export trade this year.

George W. Smith testified as to the adulteration of buckwheat flour. C. N. S. Hallberg testified as to the use of alum in baking powders.

HOW FRUIT JELLY IS MADE.

J. J. Berry, of the West Chicago Syrup-Refining company testified that most of the jellies sold on the market were fraudulent, being made of the cores and parings of apples, mixed with glucose and sugar and colored and flavored to suit. Glucose 50 per cent, sugar 10 per cent, and apple juice 40 per cent is the trade recipe for jelly.

Maurice H. Scully of the D. B. Scully Syrup Co., said that he knew of no adulterants used in the manufacture of syrup. J. J Berry, of the Chicago Syrup Refining company, gave similar testimony.

Contagious Abortion.

ED. HOARD'S DAIRYMAN:—I take the liberty of asking if contagious abortion is caught through the mouth (what is eaten or drank) or through the vagina?

Is a farm where it has prevailed safe if re-stocked?

Does the bull convey the disease and can such a bull be disinfected? P. M. LEWIS.

Certain forms of abortion are contagious—not infectious. That is, the germ is conveyed by contact and not through the air.

The germ which produces the disease will exist in any locality where it has been established. It is thought by some that if no fresh cases occur it will cease to exist in a year.

It is our decided opinion that the male can and does convey the abortion germ to the female provided he has been in contact with an infected female.

The disease evidently is not conveyed through anything eaten or drank, as Prof. Nocard in his investigations found the germ nowhere in the system of the mother except in the lining of the placenta and the bowels of the fœtus. We know of no effective method of disinfecting the male. Abortion will die out of a herd in a year or so if no fresh cases are brought in to keep the germ alive and active.

In at least 80 to 90 per cent of the cases they become immune after a year or so. With some they become barren. When it occurs in a herd, cows sometimes become barren without aborting, through the effect of the germ.

We have been of the opinion for some time, that the scours which occur in calves two to four days old, is due to the abortion germ which Prof. Nocard found in the bowels of the fœtus in all cows where the mother was affected. About the only thing we can do with this disease is to keep it from spreading and wear it out.

Cheese Factory Grants.

The department of Agriculture of the Province of Quebec, in order to encourage the building of first class cheese factories and the manufacture of first class cheese is offering grants or subsidies, ranging from $100 to $200, to factories in the Province of Quebec. The conditions upon which the subsidies are granted are down in a little book just issued by the Department, and are divided into four categories, viz:

Those relative to the construction of the factory, and to that of the curing room in particular; those relating to the ventilation of these rooms, to their cooling in summer, and their warming in the spring and autumn; those which concern the general laying out of the factory; those which relate to the manufacture and to other questions. The book also contains a great deal of information regarding the making of cheese and the building of factories, which would be of value to cheese makers throughout the province.—*Montreal Quebec Star.*

CONCERNING OUR ADVERTISERS.

THE WORLD'S RECORD FOR OUTPUT.

Adding together the actual number of the different kinds of harvesting machines made in a single day during 1898, at the works of the Deering Harvester Company of Chicago, gives the enormous total of 1,319, or more than two complete machines for each working minute.

THE KIND OF FARMING THAT PAYS.

Of all the improvements that have been made in farming methods and farm implements, none will do more to add to the farmer's prosperity than the perfecting of the flat, spring tooth weeder. The results of using this implement are thus summed up by Mr. Henry Walter, Shermerville, Illinois:

"I have tried Hallock's Success Anti-Clog Weeder and Cultivator on oats, peas, potatoes, feed and field corn, always with the very best results. Beats any farming tool ever known here for pulverizing the soil and destroying weeds. I have tried the weeder where a lever harrow would not work, ground being too hard and baked from rain. Never before saw such work. It looked like a garden patch worked with a garden rake. I also tried it on plowed ground just before planting. Worked to perfection, smoothing, pulverizing and leveling the soil like a house floor. The weeder is a wonder to all who see it work. It is the greatest labor saving tool ever introduced to farmers of this country. I have put it through all kinds of trial on different crops, and it has not failed in a single instance."

The Electric Wheel Company, the well known manufacturers, of Quincy, Ill., the builders of Electric Low Down Handy Wagon and the Electric Steel Wheels, have extended their business.

They are now manufacturing in addition to the above, a complete line of "electric" Dairy Supplies and Appliances. This line embraces milk coolers and aerators, cream separators, feed cookers, galvanized steel stock, water and sheep dipping tanks, stock feeding troughs, etc. These people are so well known to our patrons as to need little commendation from us, and it is entirely safe to say that in the manufacture and sale of this new line of goods. They will sustain the reputation for high quality of goods and honest and fair dealing which they have made in the past. Should any of our readers be needing goods of this kind they will do well to ask for the "Electric" Line catalogue.

Horse Owners! Use

GOMBAULT'S

Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.*

Every bottle sold is warranted to give satisfaction Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars.

THE LAWRENCE-WILLIAMS CO., Cleveland O.

CANCER cured at home. Send four cents, stamps. 80 page book, illustrated Dr. J. B. HARRIS, 2226 Kemper Lane, Walnut Hills Cincinnati, O.

SCHMIDT'S Treatment for Milk Fever

The new remedy that has a record of 90% of cures in 412 cases. Two complete treatments with full directions and necessary apparatus neatly packed in a box for shipment, Price $2.75. Every dairyman should have this outfit on hand ready for instant use Order at once from

GARDINER BROS., 220 E. Preston St., Baltimore, Md.

ABORTION!

Retention of Placenta and Failure to Breed.

H. W. KELLOGG'S experience with and positive cure for these diseases in cows. Send for circulars. Address all communications to

H. W. KELLOGG COMPANY, Ripon, Wis

ANTIABORSIO.

WILL PREVENT ABORTION in cows and cure scours in calves. One gallon will treat twenty cows three months.

Our Specific No. 1: Absolutely prevents Hog Cholera and Swine Plague, and will cure 90 per cent. of sick hogs

Our Specific No. 2: Prevents and cures Roup and Gapes, and kills Vermin on Poultry, also kills Ticks on Sheep. These are established facts, not experiments.

Our remedies are liquid germicides applied by sprinkling in closed stables and pens. Cures by inhaling fumes which destroy the germs of disease.

Send for free booklet and testimonials.

Animal Germicide Co., 319 Washington St., N. Y.

Dr. Horne's Anti-Abortient

Prevents Abortion and cures Nymphomania—failure to breed; also Emmenagogue Powders for cows failing to come in heat. Both powders are the result of long practical experience and study and may be given in a little moist feed. 5 oz. $1, 11 oz $2, 23 oz. $4, 50 oz. $8, by mail.

Also Specific for

SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM. HORNE, Janesville, Wis.

THE Texas State Dairymen's Association proposes to know just what are the facts about the average production of cows in milk, cheese and butter, and the real cash value of the same. To this end they have appointed Mr. John Jephcott to gather accurate statistics of all dairy cows and their products in the county of Grayson.

Returns from a Tennesee Dairy.

ED. HOARD'S DAIRYMAN:—Thinking that it might be of some interest to some of your many readers, I would give my experience as a junior patron of a first-class Creamery Co. I live in the southern part of middle Tennessee on the L. & N. R. R., two and one-half miles from the county seat of Giles County and own one-hundred and fifty acres of land. On Aug. 22, 1894, I began hauling milk to the Pulaski Creamery and have steadily improved my herd from the time I started, to the present.

Following is the statements of my product from my cattle for two years beginning Jan. 1st., 1897, and ending Dec. 31, 1898. For the year 1897, I milked an average of ten cows.

	Lbs. M'k.	*Test.*	*Amount Paid.*
January....	2,759	4.3	$23.77
February ..	3,225	4.5	32.51
March	3,330	4.5	33.70
April	5,178	4.	41.42
May	7,580	4.2	56.85
June.....	7,645	4.4	56.44
July.....	7,073	4.5	52.44
August.....	7,008	4.4	49.05
September.	5,477	4.6	46.50
October....	5,052	5.15	52.03
November.	3,619	6.14	46.68
December .	3,229	5.41	39.02
Total....	61,175	Av. test 4.7	$530.41

I had no silo until the fall of 1898. I built one of 2X4 pine staves dressed and tongued and grooved, fifteen feet in diameter and 24 feet high, 5 feet in the ground with rock foundation; cost one hundred and ten dollars complete. Any man is not in the dairy business unless he has a silo; it certainly affords more nutritious feed for the amount of money invested than can possibly be procured otherwise.

My 1898 statements with an average of 16 cows are as follows:

	Lbs. M'k.	*Test.*	*Amount Paid.*
January....	3,879	5.90	$54.32
February ..	4,604	5.90	50.42
March.....	5,664	5.66	66.26
April	6,458	5.66	70 39
May	10,007	5.17	91.31
June.....	9,856	5.90	102.94
July.....	8,878	5.17	75.32
August.....	8,223	5.66	85.06
September.	7,556	5.90	84.91
October....	7,154	6.39	83.54
November.	6,031	6.14	65.89
December..	7,072	6.39	89.81
Total	85,382	Av. test 5.82	$920.17

My cattle average me for 1897, $53.04 each and for 1898 they averaged $57.51 each.

I am not using any science in dairying; am trying to improve my herd by breeding the best bulls I can get to good grade cows. I have the Jersey breed. I would be glad to see other statements from other sections so as to compare. T. L. SMITHSON.

Pulaski, Tenn.

Sell Milk or Cream?

The question is the profit in milk at 4 cents per quart, or cream at 20 cents per quart, and the skim milk to be fed to calves and pigs. To decide such a proposition as this, it is necessary to take into consideration several things that do not appear on the sur face. With milk at 4 cents per quart we have a very plain case, which is simply the matter of receiving a certain amount of commodity. But with the question of selling cream at 20 cents per quart and the added value of the skim milk, we are confronted with quite a complicated problem of values. Before one could accurately get the number of quarts of cream in 100 quarts of milk—which a computation of values demand—it would first be necessary to know just what the percentage of the cream is; "cream" being a somewhat indefinite term. But we can form a basis of calculation on the average cream put on the market, which is in the ratio of one quart of cream from six quarts of milk. The six quarts of milk would be worth 24 cents, and the one quart of cream 20 cents. But to this 20 cents must be added the value of the skim milk, which from the experiments of some years has been proved to have a value of, at the lowest figure, 10 cents per 100 pounds. This is its value simply for feeding, that is, for what it will make in pounds of pork or growth of calves, and does not take into consideration the manurial value. From experiments made at various times the value in fertility of skimmilk has been fixed at two dollars per ton. This value perhaps, by skillful and judicious handling, and if the manure is used as a component part with other fertilizers, may be increased. After several years of experience in feeding skimmilk, the writer has found that if used for feeding to cows, its value is nearly double what it is if fed to calves or pigs.

But aside from the comparison of values of milk at 4c and cream at 20c and the feeding of skim milk, comes in the question of cost of labor and outht necessary in the two plans. This is a consideration that does not appear in the present proposition. Here then will be the figures from the two plans proposed: One hundred quarts of milk at 4c per quart will amount to $4; from this, at a ratio of one quart of cream from six quarts of milk, we have 16 2-3 quarts of cream, which at 20c per quart would amount to $3 33 1-3. Taking this quantity of cream from the 200 lbs. of milk (100 quarts or approximately that amount), we have 166 2-3 lbs. of skim milk, which, at 10c per hundred pounds, would make about 17c to add to value of cream, which will make $3.50 2-3. This is the comparison of values, without computing the manurial value of the skim milk, which is at best an indefinite matter, and can be estimated on a basis of about 68 per cent of its value being retained in the voidings of animals to which it may have been fed.—*Country Gentleman.*

Effect of Concentrated Foods on the Production of Milk.

In *The Journal of the Board of Agriculture*, for December, 1897, an account was given of the results of an experimental inquiry, carried out by Mr. John Spier on behalf of the Highland and Agricultural Society to ascertain the effects produced by various kinds of what are known as "concentrated" foods upon the milk yield of cows, and upon the butter manufactured from the milk of cows which received such foods. The foods employed in this investigation included vetches, maize, beans, oats, linseed and cottonseed cake, grey peas, sugar meal, meat-meal, brewers' grains, and mixtures of grains, bran, treacle, and potatoes. The principal conclusions deduced were that rations with a very high albuminoid ratio seemed to have a depressing effect on the milk yield; and that, provided extremes be avoided, the dry matter in the food seemed to be the chief controlling factor in the production of milk or increase of live weight, and was of greater importance than the albuminoid ratio. It was also found that every food when first given, seemed to have more or less effect in increasing or decreasing the percentage of fat in the milk; but that this effect was transitory, and that the milk returned to its normal composition about the end of the fifth week—brewers' grains in the wet state and in excessive quantity were, however, excepted from this general statement. The decrease per cent in the flow of milk below the estimated normal yield during the periods when foods possessing a high albuminoid ratio were supplied to the cows was calculated to be as follows: Vetches, 38.5; beans, 24.0 and 14.8; decorticated cotton cake, 15.8; decorticated cotton cake and meal, 8 3; cummins, 23.3.

Experiments of a somewhat similiar character to those referred to above on the rational feeding of milch cows have been carried out on a more elaborate scale for some years past at the physiological experimental station of the agricultural academy at Poppelsdorf, Bonn, by Drs. Hagemann and Ramm; The object of these experiments was also to determine the influence of concentrated foods on the production of milk. In the more recent of these investigations, which were under the direction of Dr. Hagemann, the special foods submitted to trial were maize, rye, wheat pollards, cottonseed meal, bruised barley, malt sprouts, palm-nut cake, and molasses, in addition to the ordinary provision of hay, straw, and roots. The proportions of the articles constituting the ordinary ration varied with the nature of the concentrated fodder: the daily allowances were as follows:—Hay, from 11¼ lbs. to 13¼ lbs.; straw, 2 lbs. to 6 lbs.; and roots, 48¾ lbs., to 61½ lbs. In addition to this standard keep there was given at different periods, one of the following rations:—13¾ lbs. of maize; 11¾ lbs. to 13¼ lbs. of wheat pollards; 12 lbs. of rye; 5½ lbs. of rye and 4½ lbs. of palm-nut cake mixed; 3¾ lbs. to 4¾ lbs. of cottonseed meal; 9 lbs. to 10 lbs. of malt sprouts; 8 lbs. to 10 lbs. of bruised barley, mixed with 4 lbs. to 6 lbs. of palm-nut meal; and 7¾ lbs. of molasses mixed with other foods.

In summarizing the results of his experiments, Dr. Hagemann states that the production of milk proved to be dependent in certain respects upon the nature of the food supplied to the cows, but not, as is usually supposed, solely upon the albuminoid ratio. If the foods employed are classified according to their apparent average influence in increasing the yield of milk, irrespective of its fat contents, his report gives the following order: maize, wheat pollards, malt sprouts, earth-nut cake, cottonseed meal and rye and palm nut cake mixed. It will be observed that the highly albuminous rations of oilseed cakes and meals were less effective in increasing the flow of milk than the other foods named. With respect to the fat contents of the milk, the oil cakes rank before the other foods; the order under this head working out on the average, as follows: Palm-nut cake and rye mixed, cottonseed meal, earth-nut cake, maize, malt sprouts and wheat pollards. The results obtained with rye were conflicting.

The object of these experiments was, however, not merely to test the effects of the use of various concentrated foods upon the secretion of milk, but also to ascertain which of those foods furnished on the whole the largest margin of profit. Hence, with a view to determine the economic value of the several foods, Dr. Hagemann compares the value of the milk produced in separate periods during which the respective foods were employed, with the cost of each ration Judged from this standpoint, the results of the experiments are stated to have shown that maize is in every respect a profitable food for milch cows, both as regards its influence on the quantity and quality of milk produced, and on the production of meat. Next to maize the following foods are placed in order of value: Wheat pollards, cottonseed meal, and earth nut cake. Molasses was found to have a stimulating effect on the milk glands; the cow receiving molasses yielded for a time more and richer milk than the known constituents of this ration would lead one to expect, but there was a marked reaction when the molasses was withdrawn, in spite of the substitution of other fodders containing high percentages of albuminoids. Moreover, it was found that molasses augmented the secretion of urine by about 50 per cent., and Dr. Hagemann considers it probable that continued feeding with large quantities of this article would bring about disturbances of the heart and kidneys.

KIDNEY TROUBLE.

The Most Prevalent, Dangerous and Deceptive Disease.

Thousands Have it and Don't Know it.

Pains and aches come from excess of uric acid in the blood, due to neglected kidney trouble. Kidney trouble causes quick or unsteady heart beats, and makes one feel as though they had heart trouble, because the heart is over-working to pump the thick, kidney-poisoned blood through the veins and arteries.

Soreness or uncomfortable feeling in the back indicates kidney trouble of no small importance.

The passing of scanty or profuse quantities of urine is a warning of kidney trouble. If you want to feel well you can make no mistake by first doctoring your kidneys.

The famous new discovery, Dr. Kilmer's Swamp-Root, is the true specific for kidney, bladder and urinary troubles. It has cured thousands of apparently hopeless cases after all other efforts have failed.

Sold on its merits by all druggists in fifty-cent and one dollar sizes. A sample bottle sent free by mail to any address. Also a book telling all about Swamp-Root and its wonderful cures. When writing, address Dr. Kilmer & Co., Binghamton, N. Y., and mention that you read this generous offer in HOARD'S DAIRYMAN.

Volume XXIX of Hoard's Dairyman

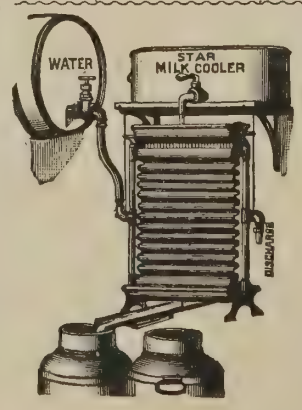
JERSEY CATTLE SALE.

Kirkmont Herd At Auction!

TUESDAY, JUNE 6th, 1899,

Commencing at 1 p. m., at the residence MARSHALL M. KIRKMAN,

Corner Ridge Avenue and Lake St., EVANSTON, Cook Co., Illinois.



(Four miles north of Chicago.)

The Herd is made up of 22 members of the Stoke Pogis family and 15 of the Stoke Pogis-Landseer families, and has been built up with the one object of developing a TYPICAL DAIRY COW.

It consists of 24 Cows and Heifers. The service bulls, **IDA'S RIOTER OF ST. LAMBERT 24th** and **AARON'S RODNEY**, represent the choicest Stoke Pogis blood, and, therefore the highest type of Jersey. Every animal is registered in the American Jersey Cattle Club. The young bulls that will be offered are sired by the service bulls and are from the cows offered. They are worthy to head any dairy herd. Every cow in the list is a good breeder, gentle, a persistent milker and will make 4 5% test in butter fat. The Heifers are splendidly bred (from the sires and dams to be sold) and give every assurance of making choice cows. The herd will not be fitted up for sale, but will be offered on its merits as one of the best in the world. Each animal is guaranteed free from tuberculosis, and is subject to transfer in the American Jersey Cattle Club.

TERMS CASH, or 30-day bankable paper. 1429 Ridge Ave, EVANSTON, ILL.

Star Milk Aerator AND COOLER.

If you have milk worth cooling at all, it is certainly worth while to cool it thoroughly. An efficient Milk Cooler will cool to within two degrees of temperature of water used; the Star does this and also **AERATES.**

If you would like to know the reason why, send for 1899 Catalogue of Sanitary Dairy Apparatus.

To be had for the asking.

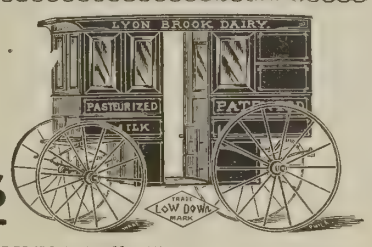
STAR MILK COOLER CO., Haddonfield, N. J.

A Perfect Milk Wagon

On a Perfect . . .

Short Turning Gear

We make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.



Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

There Are Others

But they all came after ours.

WE ARE THE ORIGINATORS

Of the now famous "LOW-DOWN" Milk Wagon.

Imitation is an acknowledgement of real merit. Thirteen years' trial has proven the Parsons "Low-Down" Wagons to be **THE BEST.** Secure our catalogue of strictly first-class, hand made, up-to-date, durable work.

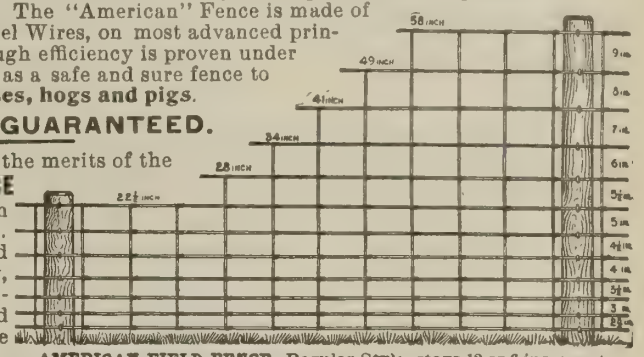
O. T. ROGERS & SONS, Detroit, Mich., U. S. A.

We are the only firm that builds factories complete, put them in operation and guarantee results.

Melts in Your Butter

quicker, easier, better than any other salt ever made. That's the reputation of Diamond Crystal Salt. It lives up to its reputation. The reason is that

Diamond Crystal Salt



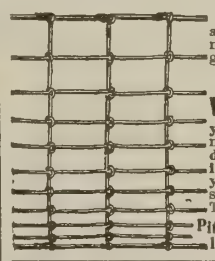
is composed of flakes, not grains. It dissolves not only quickly, but entirely. No waste of labor or time. The salt is all in the butter and the butter is the better for it. Send for book about the "*Salt that's all Salt.*"

DIAMOND CRYSTAL SALT CO., St. Clair, Mich.

THE FENCE THAT FENCES.

"AMERICAN" ALL STEEL WOVEN WIRE FIELD FENCE.

Large, strong wires heavily galvanized. **Tension curve** at every intersection of main strands and stay wires, provides for expansion and contraction. The "American" Fence is made of Best Bessemer Steel Wires, on most advanced principles. Its thorough efficiency is proven under all circumstances as a safe and sure fence to **turn cattle, horses, hogs and pigs.**



EVERY ROD GUARANTEED.

INVESTIGATE the merits of the **AMERICAN FENCE** at our agency in your nearest town. If you can't find such an agency, write us for complete catalogue and we will see you are supplied.

AMERICAN FIELD FENCE, Regular Style, stays 12 or 6 ins. apart.

AMERICAN STEEL & WIRE CO. General Offices: **CHICAGO, ILL.**

EXPENSE OF REPAIRS.

The repairs of an inferior article soon make it cost more than the first price of a good article. When you buy

PITTSBURG WOVEN WIRE FENCE

you stop all repair. It doesn't need repairs. It is **strong, durable** and **lasts indefinitely.** We want an agent in your locality. First order secures township agency. Terms and circulars free.

Pittsburg Woven Wire Fence Co 17 Penn. Av., Pittsburg, Pa.

CYCLONE FENCE MACHINE

Builds 100 RODS of strongest fence a day, 27 to 60 inches high. 7 to 12 cables. Easy to Build and Cheap. Thousands in use. Fence material at wholesale prices. Write for catalog.

CYCLONE FENCE CO., HOLLY, MICH.

Branches: { Waukegan, Ill. Cleveland, Ohio. / Toronto, Can. Melbourne, Australia.

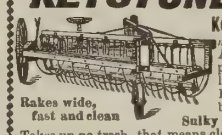
REPAIRING NEATLY DONE

is an obsolete phrase on the farm where **Page Fence** is exclusively used. **It takes care of itself** "while you wait."

PAGE WOVEN WIRE FENCE CO., ADRIAN, MICH.

IRON PIPE AND FITTINGS

ONE INCH BLACK WROUGHT IRON PIPE



For Steam, Gas and Water. Good as new. Tested, Re-painted, Re-threaded and couplings furnished. Ranging in lengths to 20 feet.

TWO CENTS Per Foot.

Write for free catalogue of merchandise for ***HOME, FARM and FIELD***---from **Sheriffs'** and **Receivers' sales.** Roofing, Plumbing Material, Hardware, Clothing, Dry Goods, Boots and Shoes, Tools, Machinery, &c., &c., &c., **at HALF PRICE.**

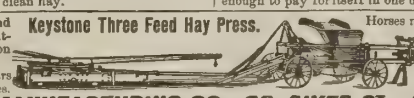
Chicago House Wrecking Co. W. 35th & Iron Sts. CHICAGO.

KEYSTONE QUICK HAYING MACHINES.

Keystone Side-Delivery Rake

means "Quick Haying, Quality Prime." Turns the hay completely and leaves it in a light, loose windrow ready for loader. Its use means **air cured,** not sun bleached hay. **Better than a Sulky Rake and saves use of tedder.**

Rakes wide, fast and clean



Takes up no trash, that means clean hay.

Keystone Hay Loader.

Loads the hay from the windrow or cock, or direct from the ground if the hay is heavy. Takes the hay up clean but takes up no manure, rubbish, &c. It makes haying quick and easy. In showery weather it often saves enough to pay for itself in one day. Loads a wagon in 5 minutes.

Keystone Three Feed Hay Press.

Made entirely of steel and iron. Horse power only. Mounted on steel wheels, and stands on the wheels when operating.

Write for our special circulars fully describing these machines.

Horses move in a full circle. Each revolution moves the plunger three times---**one more feed than any other press made.** Requires no more men but increases capacity beyond comparison.

KEYSTONE MANUFACTURING CO., 39 RIVER ST., STERLING, ILL.

THE NEW BOOK Feeds and Feeding

By Prof. W. A. HENRY.

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

EVERY SUCCESSFUL farmer who raises fruits, vegetables, berries or grain, knows by experience the importance of having a large percentage of

Potash

in his fertilizers. If the fertilizer is too low in Potash the harvest is sure to be small, and of inferior quality.

Our books tell about the proper fertilizers for all crops, and we will gladly send them *free* to any farmer.

GERMAN KALI WORKS,

The Ever Increasing Demand for The Improved U. S. Separator

shows conclusively that Dairymen appreciate the worth of this machine. The sales were never so enormous as at present. To give those who are not familiar with its superior qualities some idea of what users think of it will add a few sample letters.

What the President Says.

BRATTLEBORO, VT., Feb. 27th, 1899.

It gives me pleasure to say that the dairy machinery bought of your company two years ago, including a No. 5 Improved U. S. Separator and a Pony Power, is working well and giving entire satisfaction.

The Improved U. S. Separator is doing all and even more than was claimed by your agent. The **separation is perfect**, it runs easily, without noise or friction, and it is easy to manage and care for. Of all the separators placed upon the market, there is none that excels the Improved U. S. in my opinion.

G. W. PIERCE, President Vt. Dairymen's Ass'n.

30 Per Cent. More Butter and of Better Quality.

OTIS, IND., October 4th, 1898.

The Improved U. S. Separator purchased of you has exceeded my highest expectations. In simplicity of construction and ease of running it cannot be beat. It has given us no trouble, and we have made from the start 30 per cent. more butter and that of a better quality than we did previous to obtaining the U. S.

Hoping the Improved U. S. will continue to lead, I am, etc.,

HENRY STORMES.

Excels All Others.

COLDWATER, N. Y., June 28th, 1898.

The Improved U. S. Separator is in constant use and is giving perfect satisfaction. I can say from actual experience that in ease of running, **close skimming** and quality and quantity of cream produced it excels all others. No farmer or dairyman can afford to be without one. They will pay for themselves.

C. C. BEAMAN.

Superior to Anything in Cream Separator Line.

BORDER PLAINS, IOWA, Aug. 15th, 1898.

I bought an Improved U. S. Separator this spring, and therefore have had ample time to test and also to compare it with other machines. I think the Improved U. S. is superior to anything in the line of cream separators I ever saw. For simplicity, ease of operation, thoroughness of work and substantial appearance I can recommend the U. S. I think it is O. K.

PERFECT FLAVOR IN BUTTER AND CHEESE

results from perfect milk. Perfect milk is that which has been properly handled from the moment it left the cow until it reaches the finished product.

THE PERFECTION MILK COOLER AND AERATOR

makes a perfect milk. It takes out all animal odors and those arising from stables or feed. It retards **loppering** and **souring**; prevents the **cowy odor** in butter and **deleterious gasses** in cheese. City boards of health are insisting on milk that is properly cooled and aerated. This machine is **simple, quick** and **effective.** Made in sizes from 1 to 200 cows. Send for free catalogue of **Farm** and **Dairy Supplies.**

L. R. Lewis, Mfr., Box 10 Cortland, N. Y.

Water MUST Be Hot

to properly clean and scald your milk cans, pails, strainers and bottles. With this Hot Water Stove, Circulating Boiler and Wash Box, you can have the water as hot as you want it, just when you want it. Little expense and no trouble to run it. The hot water stove, with pipes and fittings furnished separately. **Best and cheapest heater for greenhouses, hen houses or hog pens.** Write for free catalog and learn all about this and many other dairy necessities—**cream separators, milk coolers, strainers, scales and butter tools.**

Subscriptions in United States and Canada $1.00 per year; 6 months 50 cents; 3 months 25 cents.

FOREIGN SUBSCRIPTIONS may be sent through Sampson Low, Marston & Co., St. Dunstan's House, Fetter Lane, London, Eng., or their agents, including the leading news dealers and book sellers in nearly all foreign countries.

All countries in the Postal Union $2.04 a year; not in the Postal Union $2.56.

Correspondents must not expect us to acknowledge the receipt of letters containing remittances for subscriptions. The receipt of the DAIRYMAN is sufficient notification that the money has been received. The label on the paper will show date to which subscription is paid. In case of renewals if date on label is not changed within two weeks after remittance is sent, inform us at once.

Remit by draft on Chicago or New York, or Post Office or Express Order; never by personal check.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

THE co-operative creamery at Conroy, Iowa, opened on its first day with 40,000 pounds of milk. This is the largest amount of milk we have ever known a creamery to have at its first start.

A CONFLICT OF PATENTS.

About 300 farmers in the vicinity of Carthage, New York, have received notice that they are infringing on a patent milk can, or separator manufactured by the Wheeler Cream Separator company of Syracuse. They have purchased cans of the Aquatic Separator company, of Watertown, which makes a similar separator, patented by a man named Lee. There are a number of similar cans in the express office now for Wilna farmers. The notices are being served by two strangers, who claim to represent the Wheeler company. They charge $5 for a large can, $4 for a small one, and claim a number of farmers have settled.

It may be well to state that neither of the above cans can be rightfully called separators, as they are in effect, nothing but deep setting cans with the adding of cold water to the milk.

Building, Remodeling and Ventilating Barns.

(Prof. F. H. King, Madison, Wis., at the Wisconsin Dairymen's Convention.)

MR. CHAIRMAN, LADIES AND GENTLEMEN:—The short time at my disposal will make it necessary for me to present the subject in much briefer form than I had planned to do. To condense my statements as much as possible it may be said first of all, that cows require in our winter climate a warm stable. The secretion of milk in the udder can only take place under the right temperature. To set fire to a piece of wood, it is necessary to first raise its temperature to a certain point, and only after this point has been reached, will chemical action begin. The housewife when she wishes to raise her bread sets it in a warm place, knowing that only under these conditions will the chemical action involved in the fermentation processes go on.

If you wish to sprout corn, you put it in a warm soil, and only after the right temperature has been reached will the chemical action, which is the central factor in the germination take place; and so it is in the production of milk in the udder of the cow, there must be maintained in it the right temperature. To refrigerate the blood passing through the udder and the large milk arteries, lowering the temperature of the blood before it reaches the udder eight or ten degrees, would prevent the secretion of milk, no matter how well the cow was fed, for at that low temperature the blood would have to pass in and out unchanged.

Now, in the development of the dairy cow there has been evolved an abnormally large udder, exposed to the weather far more than nature ever intended it to be. More than this, you are asking her to produce milk in the cold of winter. Nature does not require this of her, but had arranged conditions so that the calf should be fed in the warm season of the year. To run an engine in the strong wind requires much more fuel even in the summer time than under other conditions, and the same principle applies in the care of domestic animals. The cow must hold the temperature of her body up to 100 degrees; she has a limited capacity only for digesting and assimilating food, and if it taxes this capacity to its full extent to maintain her temperature, she will do that first, and only when she has a reserve supply of food in her body can she produce milk. We must therefore have a warm stable as the first requisite for the proper care of cows in winter.

Next to a warm temperature in the stable, stands the demand for plenty of fresh air, supplied only by a good system of ventilation. A steam engine cannot be run without an ample supply of oxygen, neither can a cow do her best without plenty of fresh air. A man after he is through digesting his food and is at rest uses about 1,627 cubic inches of oxygen per hour, but 57 per cent more of oxygen is required to simply do the work of digestion in the case of the man when he remains at rest.

Now what we are doing with the cow is to require her to digest just as much food as she can and convert it into milk. It is plain therefore that one of the chief requisites for this is plenty of fresh air.

On an average, a 1,000 pound cow will take something like 30 pounds of dry feed per day, and she will drink about 72 pounds of water. In other words, you feed her in the neighborhood of 100 pounds a day, but the amount of air that the cow must use in order to utilize the 30 pounds of feed and the 72 pounds of water is somewhere in the neighborhood of 192 pounds, or nearly double the amount of food and water combined. I wish to emphasize the importance of this matter of the abundance of fresh air, and in order that you may realize its great need more fully I shall perform a few experiments with this lighted taper and glass jar. (Prof. King here made several experiments showing that a supply of oxygen was necessary to support the flame of the candle in the jar, and how easily and quickly it would be extinguished by pouring over it the air once breathed.

Now to apply this principle here illustrated: The cows are standing on the floor of stable, the nostrils of the cow are so arranged, that in her breathing, the air thrown out of the lungs accumulates at the floor. From where then should the air be removed? From the ceiling? No. For there is where the air is best. Not only is the purest air at the ceiling, but that which is warmest also, for the bodies of the cows act as so many stoves in warming the lower air of the stable, causing it to rise and accumulate at the ceiling, and the heat given off by their bodies is sufficient to amply warm the stable, if it is only rightly constructed and properly ventilated. If you introduce pure air from above,

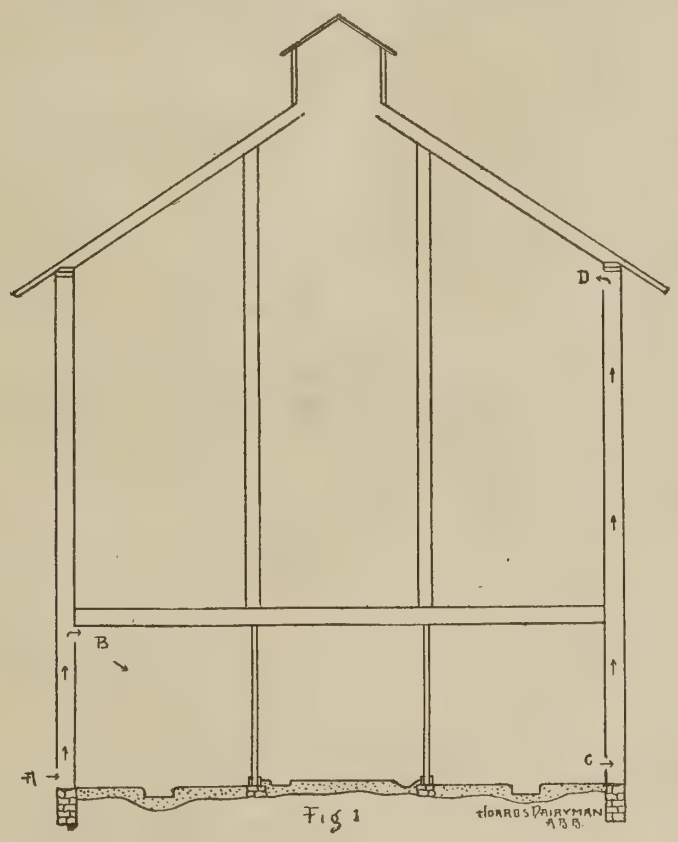

Fig 1

you bring the cold air in contact with that which has already been warmed, thus utilizing what would otherwise be waste heat, to warm the air before it comes in contact with the bodies of the cows. If the air is brought in in a large number of places around the sides of the stable, the tendency to produce a cold draft is reduced to a minimum, and the greatest heating effect is secured. Then if the bad air is removed from near the floor, the coldest air will also be removed at the the same time, and the greatest advantage is derived from the heat liberated by the bodies of the cows, and they are kept better supplied with the purest air already made warm by the waste heat from their bodies.

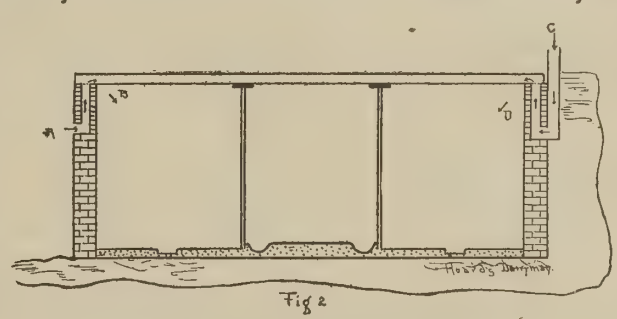

Fig 2

Ex-Gov. Hoard—How do you introduce the cold air at the ceiling and prevent the warm air from going out?

Prof. King—The method of doing this is represented on these two charts. Fig. 1 represents a frame barn built in the manner followed in ordinary house construction, where studding are used set three feet apart and the siding put on horizontally instead of up and down, as is commonly practiced in barn building. In the construction of small barns, this is much the more economical method of framing, as smaller timbers can be used and the siding does away with the necessity of braces, thus giving a much stronger structure with less lumber. Where this method of construction is followed the air may be allowed to enter the stable by passing in between the sheeting inside and the siding outside, as represented at A, just above the sill of the barn. It then rises between the studding and enters the stable as indicated by the arrow at B, thus bringing the cold air in at the top of the stable. Openings of this sort would be provided on all sides of the stable, if possible, at intervals of ten or twelve feet, and they may be about three inches by twelve inches at top and bottom, and, if desirable, can be provived with sliding or hinged valves near the ceiling to be shut if too much air is coming in, though this will not usually be necessary. To take the air out of the stable, the method represented in the right side of the drawing at C and D may be adopted. The method is simply to close up the space between two or more sets of studding from the floor of the stable to the plate in the story above, thus forming a continuous flue or series of flues through which the air may rise and escape. The air may be allowed to pass out under the roof and escape through the cupola, or a ventilating flue could be carried directly up through the roof so as to form a nearly continuous straight flue for the escape of the air rising above the ridge of the roof. This would give a stronger draught, but in small stables of less than twenty cows it would not usually be necessary to carry it out through the roof.

In Fig. 2 is represented a method of taking air into a stone basement where at A B a flue is built in the stone wall when it is put up by using six inch drain tile or a wooden form set in the wall, allowing the air to enter at A on the outside and pass into the stable under the joists at B on the inside. In case the earth rises to the level of the ceiling on the outside, then the method represented on the right side of the drawing may be used. In this case the flue is built in the wall in the same way as on the other side, but the end underground opens into a vertical shaft at C which is made of sewer tile, or a wooden column if a cheaper arrangement is desired. This duct rises just above the surface of the ground outside, and should be covered with a piece of wire netting to keep out leaves and litter.

The air should be taken out of the stable within eight or ten inches of the level of the stable floor, as represented in Fig. 1.

Ex-Gov. Hoard—Do you find some difficulty in hoisting that cold, heavy air out?

Prof. King—Not ordinarily. It is only in times of very still, muggy weather that there is any difficulty of this sort.

Gov. Hoard—Could't you increase the draft by carrying that pipe up on the inside and along the ceiling, thereby warming the current of air inside the pipe?

Prof. King—That method would help, except that every elbow that is introduced in a ventilating flue hinders the draught; the fundamental principle which should always be observed as far as possible, is to secure as straight and continuous a run as you can. In order to supply twenty cows with the amount of air they need and still keep the temperature right, there should be provideda ventilator two feet square on the inside and this should be able to carry air at the rate of three miles per hour to supply the needs of the twenty cows;forty cows would require two such ventilating flues, or a single one having double that capacity. In a well built stable, which gives ample working room, it is easy to maintain a temperature of 40° to 60° in the coldest weather with such ventilation as described.

In regard to the height of the cow stable, it should be said that this should be no greater than is really required for the comfort and ease in doing the work. You may make the room as large as you choose and as high as you choose, and if there is no provision for the air to come in or go out, it is not a suitable stable. It is not cubic feet of space which is needed, but cubic feet of fresh air, and so the stable may be made as low as practicable for the needs of workmen, and from eight to nine feet in the clear is a great plenty for the ordinary farm sta-

IF the dairyman who is content to let many dollars slide through his fingers through the manufacture of butter with dirty utensils, could only see that lost money in a pile before him, it might go a long way towards reforming his methods. But as the leak is small, he can't see how much money slides through it in a year.

A FEW days since ten Pittsburg merchants were each fined $100 and costs for selling oleomargarine. The charges were brought by the agent of the pure food commission. None of those fined were present at the hearing and judgment was given by default. Several of the defendants were represented by attorneys, but no objection was offered to the testimony of the Commonwealth's witnesses.

The "poor people" of Pittsburgh in whose interest these ten self-sacrificing merchants gave up their money, without a word of protest, must feel the force of the sublime act.

PROF. F. J. Lloyd, a prominent dairy expert, of England, makes the following statement in his report to the British Dairy Farmers' Association: "Some samples of milk have been sent me which had been stated to have caused severe sickness and purging. *In all these samples I found formic aldehyde* (Freezine)".

A few cases like the above are of more value in determining the action of preservatives than many pages of testimony from witnesses, who look at preservatives through golden spectacles and consequently see no harm from their use.

AT a recent meeting of the Board of Regents of the University of Wisconsin, Mr. Arthur G. Hopkins, D. V. M., was elected instructor of veterinary science and practice in the Agricultural College and Experiment Station. Mr. Hopkins is an Englishman by birth. Until recently he lived in Canada. He was a graduate from the Toronto Veterinary College, after which he practiced for some time in Manitoba. Later, he studied at the Ontario Agricultural College, Guelph, and is now at the Iowa Agricultural College, Ames, where he will soon graduate. Last fall he pursued a course of graduate work at the McKillipp Veterinary College, Chicago. Mr. Hopkins will assist both in instruction and experimentation at the University, his work being in the department of animal husbandry, which is in charge of Prof. W. L. Carlyle.

THERE is nothing but commendation for the business methods followed by the Osage Co-operative Creamery, whose annual report is published elsewhere in this issue.

We regret that Mr. Bartle did not have the data at hand for making the comparison between the separator and deep setting systems, and if it is all practicable for him to do so, we are sure the readers of HOARD'S DAIRYMAN would be much obliged to him for some definite information on this subject.

It seems not improper, also, in this connection to remind the occasional inattentive reader that the cost of gathering the cream, manufacturing the butter and placing the same on cars, does not include the freight to market or commission for selling. But even with these items excluded, the cost is very low indeed, and cannot be duplicated anywhere except with the very best of management.

POLLED JERSEYS.

Mr. A. V. Bradrick, editor of the *Jersey Hustler*, a wide-awake monthly published at Connorsville, Indiana, has been visiting some of the Polled-Jersey herds in Ohio, and was so much impressed with their present and prospective values that he invested in a bull and several females of that strain and has placed them in his Jersey Inn herd at Connorsville.

Frequent mention has been made of these cattle in HOARD'S DAIRYMAN and dairymen who have strong aversion to horns would do well not to forget the Polled Jerseys. This breed, if it can be called such, originated with Mr. J. R. Orr's polled cow Daisy, an unregistered Jersey, but claimed to be a full-blood, bred to a registered sire, and with Mr. C. S. Hatfield's crossing of registered Jersey sires on native mulley cows and their descendants, with the result that it is claimed the hornless tendency is so firmly established in the bulls that when crossed on cows with horns much the larger proportion of the progeny will be polled. It is further claimed that this peculiarity has been attained without sacrificing any of the dairy qualities which have made Jerseys so popular with the dairymen, and that, whether in the show-ring or elsewhere, Polled Jerseys have attained to equal honors with their horned cousins.

THE CAUSE OF TUBERCULOSIS.

Dr. F. W. Smith, of Syracuse, N. Y., has administered over 7,000 doses of tuberculin in testing the cows which furnish milk for that city. In a recent interview he was asked the following question:

"Why is it that so many cattle are now infected, when but a comparatively few years ago such a thing as tuberculosis among cattle was almost unheard of?"

"Do not think, because the disease was not recognized, that it did not exist," the doctor replied. "But I have no doubt that the modern system of close stabling has much to do with it. In the old days, when the cows slept in cold stables or ran about the straw stack in the barn-yard, the animals were hardier and freer from pulmonary disease. There is little question of that. Indeed, among the Western cattle that have never seen a stable and are shipped East for beef the inspectors rarely find any tuberculosis.

"The entire tendency of modern scientific dairying encourages tuberculosis in cattle. The animals are closely housed, given little exercise and fed on green stuff and ensilage the year round. Everything is done to increase the quantity of milk, which is naturally an increased drain on the system. Jersey cows, notably large milkers, prove more liable to the disease than native breeds. The close stabling renders the animals more liable to colds and lung troubles, and their depleted vitality makes them susceptible to tuberculosis.

If Dr. Smith had been more broadly intelligent on this question, he would not have said, without qualifications, what he did. He would have said, "close stabling" *without ventilation* for one thing.

Had he been as well posted in "modern scientific dairying" and the literature of it as he should be, he would know that most strenuous stress is laid upon the importance of securing proper ventilation in stables, without which beef cattle are just as liable to the infection of tuberculosis as dairy cattle. He should know also that Jersey cattle are no more liable than native cattle to this disease, as proved, by the experiments of the Department of Agriculture of the Dominion of Canada, and the Minnesota Experiment Station and all other thoroughly conducted comparative experiments.

It is not a question of breed but rather closeness of stabling, bad ventilation, and the presence of the infection. Given all these conditions and the big lunged beef breeds and so-called hardy natives suffer just as badly and in some instances worse than the Jerseys.

A Machine for Threshing Cow Peas.

ED. HOARD'S DAIRYMAN:—On page 276, of issue of May 19, W. H. S. has an interesting communication on cow peas and soy beans. We are particularly interested about the soy bean, both as an Illinois and a Tennessee crop. We know the Whippoorwill pea and appreciate its great value to the south, but if the soy is better, we must have a start in it this season.

Concerning the cow pea, three ingenious farmers living near here invented a successful thresher, last winter, for which they will soon receive a patent. One of the inventors informed us that the only objection offered to it was that it crushed a few seeds, but once threshing is in vogue, seed will fall in price and a few crushed peas won't amount to much; moreover, the crushed ones feed as good as whole ones.

It will revolutionize methods in the south. The one great reason people here do not sow more peas is the great cost of seed. Last year we paid $1 a bushel for seed that was fully half wasted by weevil.

Many poor farmers, especially blacks, when asked why they did not grow peas, answered: "Seed costs too much." If the landlord furnishes seed they will eat it on the table, and run planter empty over field, and then swear they won't grow—bad, but we know whereof we speak. The threshing of unpicked vines will so cheapen the price of seed that thousands of acres will be sowed where none now are.

Humboldt, Tenn. WILLIAMS BROS.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBOHYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained by some, that the fat in the milk comes, largely, from the crude fat in the food, but it has been demonstrated that it is not absolutely necessary, for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

STARTING A MILK BUSINESS.

A friend in Indiana, remitting a subscription for his neighbor, says:

"My friend is a railroad man, but owns two farms in our neighborhood, and is aiming to stock up in the dairy business, providing we can sell our milk to some advantage. He wants to know what kind of stock to commence with. I tell him to get Holsteins, as it is our aim to get a milk shipping station at Laketon. He also wants to know, how much milk a cow ought to give, and for how long a period, and at what price it can be sold. If you can give us Chicago prices for the last twelve months, that will tell the story, as the express charges will be 22 cents on each 8-gallon can. Please let me know by letter why we could not ship milk to New York. I see Elgin is making shipments there every day, and we would have about 160 miles advantage of Elgin."

That request to reply by letter has been the occasion of some delay, as we have been unable to find the time to reply, and not neglect other duties. So we say here, that every man should keep the breed of cows, which are, to him, the most attractive. Undoubtedly the Holsteins will yield more milk than the other breeds, but it will not be of so high quality, and if the day is not already here, it soon will be, when quality will be accounted worthy of consideration in making prices. Further than this, the shipping of cream is beginning to assume very considerable importance, and the richer the milk, the more cream will it yield. This is not saying that a first rate Holstein cow will not yield as much cream as a first-class cow of any other breed, but it is suggesting that even for a profitable milk business, one is not necessarily limited in his choice of breeds.

A herd of good Holstein cows should average not less than 8,000 lbs. of milk per year. We have no record of Chicago prices, but they will probably average not far from $1.00 per hundred pounds. There is no milk in its natural condition shipped from Elgin to New York, but a large amount is shipped as "condensed milk."

TO EXTERMINATE "LIVEFOREVER."

I have about two acres of land with liveforever in it. Can I kill it in any way?

I look forward to the coming of your valuable paper every week. It is very interesting. W. W. B.

Bridgeport, Conn.

Will not some of our readers, who have had experience with this pest, answer the above inquiry.

GRAIN WITH PASTURE.

Will you please give me some information on the following:

I have been feeding my cows from eight to ten pounds of the following ration: One hundred pounds wheat bran, 125 pounds gluten feed, 50 pounds wheat middlings, 50 pounds corn and cob meal, with hay, of course. Now, when turning into grass what grain ration would you advise and how much, if any, milk being my object? W. W. B.

Bridgeport, Conn.

Other things being equal, and especially if the matter of cost does not indicate otherwise, we do not believe there is any better supplemental feed for cows on good, fresh pasture, than corn and cob meal. When the

pasture becomes dry and the grass more "woody" we would mix in some bran and gluten feed and in an extreme case drop out the corn and cob meal altogether. The amount to be fed will depend entirely upon circumstances. When the pasture is abundant and cows do not have too much traveling to do, very little grain is required unless the cow is an exceptionally heavy milker.

SWEET CORN FOR SOILING.

I am going to plant some Stowell's Evergreen sweet corn to feed to my cows through the fall and early winter, if you think best to feed as late as that. I shall plant three feet each way, thin enough in the hill so it will ear good.

Now, will it pay better to feed to the cows ears and all, or would it pay better to break off the ears for the pigs? How many acres will I need for 10 cows?

Would you advise feeding grain all summer to cows? E. S. D.

Grass Lake, Mich.

Corn of all kinds, whether for soiling, for silage, or dry curing for fodder, should be planted moderately thick, so as to reduce the ears to about one-half their normal size. Thus planted, one acre of corn, with other suitable feed, will usually supply ten cows for about thirty days, and it will not be expedient to remove the ears.

In regard to feeding grain on pasture, see answer to W. W. B., of Connecticut, as published elsewhere in this issue.

A PENNSYLVANIA RATION.

Please form me a balanced ration for cows averaging in weight about 1,200 pounds, from the following feeds:

Mixed hay, clover and timothy, at $10 per ton; bran (winter wheat), $17 per ton; gluten feed, $16 per ton; cotton seed meal, $1 per cwt.; and can get hominy chop at $16 per ton, if you think proper to add the same.

Palmyra, Pa. C. A. H.

Starting with the proposition that cows should be fed all they will eat, we submit a suggestion for a minimum ration for a cow at this season of the year and capable by nature and length of time in milk of yielding a fair flow of milk, as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbo-hydrates	Ether Extract
20 lbs. clover and timothy hay	17.16	.96	7.92	.32
5 lbs. gluten feed	4.61	1 01	2.42	.25
3 lbs. bran	2.64	.38	1.16	.09
Totals	24.41	2.36	11 50	.66

Large sized cows will most likely eat more hay, and if they are exceptionally heavy milkers they might well have more grain, preserving in the increase substantially the proportions above given.

CROSSING GUERNSEY WITH RED POLLS.

Please state if it is advisable to cross a Red Polled cow with a big milk and butter record and dairy type, with a registered Guernsey sire? What kind of a dairy cow would it make, and would the offspring be hornless? F. M. L.

Worcester, Pa.

If the cow is a registered animal and can be bred to a registered sire of the same breed the resulting offspring will sell for more than if cross-bred. It is quite impossible to forecast the result of cross-breeding as indicated. Sometimes such crosses turn out excellent dairy animals and sometimes the tendency is to revert to the original type. The dairy cow of the present day is a highly organized and sensitive animal, and any departure from the general current in which she has been bred is very apt to set cross currents in motion, which will lead to so much confusion that the original impulse becomes dominant.

If such a cross should be made, the chances are that the progeny would be hornless.

PEA PODS FOR SILAGE.

L. T. A. writes us from Whittier, California, that he is feeding fresh pea pods to his cows, that the supply from a near by cannery is larger than he can use, and therefore he inquires whether they cannot be preserved in a silo. Although we have never read of any experiments in this line, there would seem to be no reason why this might not be done, unless it should turn out that the excess of water in them would tend to make the silage too sour. This can only be determined by actual trial, and we think the chances of success would justify the expense of trying the experiment. If it should fail, the silo would still remain and could be utilized for other crops.

He expresses the opinion in another part of his letter that the pea pods tend to the production of milk containing a low per cent of fat, but as he has just purchased a Babcock test, we expect he will find that feed of any kind has little or no effect upon the per cent of fat in the milk.

IODIDE OF POTASSIUM FOR LUMP JAW.

How often is iodide of potassium to be given for lump jaw? How long does it take to cure? E. C. P.

Bowers, Wis.

The dose should vary with the weight of the animal. It is one-fouth dram per cwt. of live weight, given once or twice a day in a pint of water.

After the drug has been used for a time, symptoms of iodism begin to show; there are discharges from the nose and eyes, and scaling off of the skin. On discontinuing the use of the drug, the symptoms will disappear, and the use of the iodide can be continued. The milk from cows, undergoing treatment, is unfit for use so long as the iodide is given. The proper use of the drug seems to dry up the tumor rapidly, without any effect on the animal. The length of time necessary for a cure depends on the animal and the progress of the disease.

THE WISCONSIN CURD TEST.

Will you please explain what is meant in T. B. Miller's talk on cheesemaking by the Wisconsin Curd test? E. A. L.

Ontario.

In the Wisconsin curd test, small samples of milk are taken and treated in the same manner as when milk is made into cheese. The work is done in pint Mason fruit jars. After the curd is formed the jar and curd are kept at a temperature of 98° for from 6 to 12 hours and then examined. Any impurities in the milk which will cause the cheese to be of poor quality are then made evident by the formation of pin holes or offensive odor. A full description of the test can be obtained from the bulletin issued by the Wisconsin Agricultural Station, on the Wisconsin Curd Test.

FROM CALF TO COW.

I have seen nothing in your paper, since I have been getting it, in regard to the proper feed for heifer calves from the time they are dropped till they are first fresh. I know it is very important. Give me, and your other new subscribers, some light. W. S. H.

Mattoon, Ill.

W. S. H. could not write as above after receiving last week's paper and reading the very excellent article from a New York correspondent on page 268.

ENLARGING TEATS.

I have some grade Jersey calves, heifers and cows, besides some beef cows that I'll sell as soon as they get fat and fail to give enough milk to be profitable. Part of my young Jersey cows have too small teats to milk easily. How can I remedy the difficulty? I know that letting a good sized calf run in the pasture with them will draw their teats down, but is it good for the heifer? I could let a calf suck the last 4 or 5 months before the heifer is due to drop her second calf. W. S. H.

Mattoon, Ill.

We have never been very successful in attempts to enlarge the teats. As the heifers get older the teats will naturally enlarge, more or less, and we should rather depend upon this than run the chances of injury from letting the calf run with the cow. These heifers ought to be giving a profitable amount of milk during the last 4 or 5 months of their first milking period,—certainly up to within one month of the proper time for going dry. During that last month probably no serious injury would result from experiment with a calf as a teat developer.

A CALIFORNIA RATION.

Please form a ration for me of alfalfa hay, corn ensilage, bran and corn fodder.

Round Valley, Cal. W. D R.

Having silage and corn fodder it is some what strange that there is not also some corn, which, ground with the cob, would be better than bran to go with alfalfa hay. However, taking the materials named we suggest as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbo-hydrates	Etker Extract
12 lbs. alfalfa hay	10.99	1.32	4.45	.14
6 lbs. corn fodder	3.47	.15	2.08	.07
20 lbs. silage	5 38	.26	2.80	.14
6 lbs. bran	5.29	.75	2.32	.18
Totals	25.13	2.48	11.65	.53

CEMENTING A SILO.

We have a circular stone silo, 26 feet deep and 20 feet in diameter. The stone is porous and absorbs moisture, and the floor or bottom of silo is moist. Now, would it be advisable for me to cement this silo, cement costing in this place $11 per bbl? Please give me directions for cementing the same, and about the number of barrels necessary.

Round Valley, Cal. W. D. R.

It is an essential requisite of a good silo that it be smooth on the inside. This is one of the reasons for plastering the inside of stone silos, and of course the character of the wall has much to do with the amount of mortar required. If it is rough and full of large indentations, more will be required than if it is now comparatively even. Indeed, if the wall is now smooth a cement wash put on in two or three layers might suffice. It is therefore quite impossible to estimate the amount of cement that will be required, without full knowledge of the condition of the wall. Any local mason should be competent to answer the question. With good cement, a mixture of one part cement to two parts sand makes a good mortar for the purpose.

TREAD POWER FOR SEPARATORS.—GUERNSEY MARKING.

Can a separator be successfully run with a two horse tread power? Can you give the names of some of the best make of separators? Do any of the full-blooded Guernsey cattle have a black nose with a frosted muzzle? R. B. H.

N. Y.

It depends on the size of the machine. With the larger sizes the power would be too irregular to be satisfactory. You will find the names of the different makes in the advertising columns of the DAIRYMAN.

Yes, but it is considered a fault in the markings, and avoided as much as possible.

PATRONS AND THE BUTTER.—SAMPLING CREAM.

I should like to inquire through the columns of your paper if, in running a creamery, and charging for manufacturing system, is it adviseable to allow the patrons to draw their butter and dispose of it, provided they do not sell below the market price.

I should also like to enquire the best method of sampling cream received from a hand separator daily. Would it be necessary to test a sample each day or could the samples be saved for a number of days by means of a preservative and then tested?

Idaho. SUBSCRIRER.

Unless there is some provision in the articles of agreement to the contrary, a patron can draw his butter and sell it for any price he pleases. But it is not to the benefit of the creamery business to allow such methods to prevail.

The best way to handle cream is to test each batch, otherwise the large amount of fat present is liable to cause mistakes. Of course, composite samples can be taken if great care is used, but to get correct results a certain per cent of the weight of cream must be taken for each sample and the work of sampling would be nearly as great as that of testing. The cream to be tested should be weighed out instead of being measured. This necessitates the use of fairly delicate scales, but it is necessary, if accurate work is to be done.

SOME AUSTRALIAN QUESTIONS.

Please find enclosed $2 00 for the renewal of HOARD'S DAIRYMAN, and with it may I be permitted to ask you some questions? The distance is so great, and the length of time it takes to get an answer, so considerable, I trust you will excuse me for asking too many.

How does the escutcheon, or milk theory work out in America? Is it reliable?

Could you give a description of some of the fancy dairies, such as the Darlington and other noted dairies, including the cow, the feeding, barns and dairy, also the marketing of the butter?

What is the price of a top notch dairy bull or heifer? T. L. ROGRRS.

Victoria, Australia.

1. It happens that the above questions come into hand immediately after writing the reply to the inquiry concerning the Guenon theory, contained in the letter from Florida, and we beg to refer Mr. Rogers to what is said there, and adding here that in the official scale of points, adopted by the Holstein-Friesian Association of America, for judging Holsteins, the escutcheon is given eight points out of the one hundred, which denote perfection. This is so far as we now recall the only official recognition accorded the escutcheon as an indication of dairy merit.

2. It further and quite opportunely happens that before receiving Mr. Rogers' letter, the article in another column descriptive of the Darlington dairy, had been put in type, and a reference to it will show, as HOARD'S DAIRYMAN has so often contended, that in dairying as elsewhere, it is the man himself that is the key of and index to the situation. Given the right kind of a man, and the best of butter can be made, no matter how primitive and inadequate the accessories and surroundings. The best cows and the most complete outfit of buildings and machinery in the hands of an inattentive man will not equal in profit or quality of product the result from common cows and inadequate equipment, with the right kind of a man to handle them. Not that good cows and good buildings and modern dairy appliances are undesirable, or do not contribute, when properly used, to larger success, but they cannot take the place of the intelligent, reading, thinking, studious man.

3. The prices of breeding stock are very variable, depending largely upon the reputation of the breeder, and the herd from which they are selected. One may buy first class animals for $100 and sometimes for less, or he may pay as high as $1,000.

SCALDING CHURNS—TIN LINED CHURNS—RED POLLS AS MILKERS.

What is the scientific object of scalding a churn directly before putting the cream in?

Would a tin lined churn be practicable? If not, why?

Do Red Poll cows have good records as milkers? C. B. T.

Clay Co., S. D.

The reason for scalding a churn is to insure cleanliness and freedom from any foreign odor before the cream is put in. If the churn is clean and one is sure of it, the only reason for using hot water would be to wet the wood of the churn thoroughly and rapidly, so that the grain of the wood will swell and keep the cream and butter out of the pores. But as one can never be sure of the purity of a churn, especially if it has been allowed to stand, it is always well to scald it before using. All wooden dairy implements must be thoroughly wet before being used, to prevent the butter from sticking.

The objection to a tin lined churn would be the butter sticking to the tin.

There are a few Red Polls that have excellent milk records, but as a rule they are much below the dairy breeds.

Building, Remodeling and Ventilating Barns.

(Continued from Page 287.)

ble. If you carry it up higher, you increase the amount of surface exposed, and the amount of space which the cows are obliged to keep warm; you increase the tendency of the warm air to escape above the cows, and so in every way make it more difficult to keep the stable warm.

A member—Should the intake and the outtake pipes be of the same size?

Prof. King—No. The intake pipes will have much less cross section than the total cross section of the ventilator.

Ex Gov. Hoard—You will partially create a vacuum by rushing the air out, and that helps the intake.

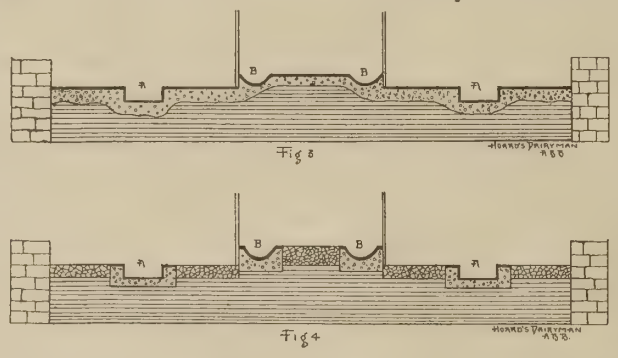
Prof. King—Yes, and the air expands when warmed by the cow, and must have a larger space to pass out through, and then there are inevitable leaks through windows and doors through which some air will enter. This point must be kept in mind for ventilating shafts:—The best ventilating shaft is such as would make the best chimney. If you understand what are the essential conditions of a good chimney you may apply them in constructing a ventilating shaft.

Ex-Gov. Hoard—There is one factor in a chimney that makes it a ventilating shaft, that is the fire.

Prof. King—That is true, and the heat from the bodies of the cows, in a measure, acts in the same way; but you are all familiar with the fact that on a windy day the air currents passing across the top of a chimney tend always to produce a stronger draught, and all good chimneys have a draught through them even when there is no fire, and the same thing would be true of a properly constructed ventilating shaft which is air tight from top to bottom except where openings are provided; the air blowing across the top acts like an inspirator tending to draw the air out.

Passing now to another point, that of light. It is of course essential that an ample amount of light be provided, but this is not so important a factor as to exclude the use of basement stables. I believe that our dairymen in Wisconsin, who have good conditions for utilizing a basement stable, should always use them rather than to abandon the idea on the ground of insufficient light. It is possible in the construction of almost any basement to introduce a large amount of light and yet get the advantages of the basement as well. The idea that a basement is damp and unhealthy grows simply out of the fact that it is possible to make the basement tighter than ordinary above ground structures, but this simply means that it is a better stable, provided it is properly ventilated, for when ventilated it will not be damp.

With the basement stable it is possible to place the silo deeper in the ground; it is possible to store the feed above more cheaply and handle it more cheaply, and it is possible to have a warmer stable, so that ordinarily where good conditions exist for the construction of the basement stable for a dairy barn, they should be utilized.



A few words in regard to the stable floor of a dairy barn. Everything considered, a good cement floor is the safest, best, and in the long run, cheapest. Such a floor can easily be kept sweet and clean; it will wear for an indefinite period if it is properly made out of good material. The first cost will be somewhat more than that of other kinds of floors, but if a man has a little tact, and uses his own ingenuity and his time, he can build a good cement floor himself, at least by hiring a good mason to work with him, and in this way get a cement floor that will cost within less than twice that of a reasonable wood floor, and when made will be permanent. The slipping on the cement floor can easily be avoided by leaving the surface a little roughened, and it will seldom be as dangerous as the wet oak floor often is.

Ex-Gov. Hoard—A little land plaster sprinkled on the floor every day will help to prevent slipping.

A member—How about cement floors in very cold weather?

Prof. Henry—The other day three farmers came to Madison, on the coldest day we have had this winter, and they came to see the cement floor in the University barn. They all went back expressing great satisfaction with that cement floor.

Prof. King—A cement floor tends even to hold the temperature of the stable higher in cold weather rather than lower, because it conducts the heat from the ground up into the stable. The mistake has been made of putting cement floors in stables with very high ceilings, and under these conditions when the walls of the stables are poorly constructed the floors may become cold, and when there is poor or no ventilation they condense the moisture of the stable and become wet, the moisture even settling and sometimes freezing. Under these conditions it is sometimes said that such floors draw the moisture up out of the ground. This, however, is not true. The moisture is simply condensed out of the air and thus the air of the stable made drier than it would have been if the floor had been of wood. The water that condenses in a stone basement or on the walls of any stable should be looked upon by the owner as a positive proof that the stable is insufficiently ventilated. There is not enough fresh air passing through the stable to remove the moisture given off from the bodies and lungs of the cattle. Again, when the stable has a strong odor of ammonia or a bad odor of any sort, this is another positive proof of insufficient ventilation, and when the cows are kept under such conditions, they are working at a disadvantage and are wasting food. The food they eat will simply pass through the alimentary canal without being digested or assimilated, for a cow will not load up her system with food if there is not a chance of getting an abundant supply of air with which to utilize it, and to remove the waste it will entail, from her body. Under such conditions therefore, you may feed your cows the same quantity of feed and yet realize from them less milk.

In figure 3 is represented a cross section of cement stable floor. Such a floor when made out of crushed rock, sand, gravel and Portland cement, making a total thickness for the body of the cement an average of four inches when thoroughly packed, and a surface finish of Portland cement half an inch thick would require, for 100 sq. ft., the following amounts of material: 1.1 bbls. cement, 1.25 cu. yds. crushed rock, 7 cu. yds. gravel, 5 cu. yds. sand. The cost of the material for 100 sq. ft. of such a floor would be, for cement, at $3 per bbl., $3.30; crushed rock at 80 cents per cu. yd., $1.00; gravel at 50 cents per cu. yd., 35 cents; sand at 50 cents per cu. yd., 25 cents, making a total of $4 90 per 100 sq. ft., as the cost of the material. If a wood floor 2 inches thick were provided for the stable, using 2x6 joists placed 16 inches from centre to centre, and with lumber at $15 per thousand, the cost per 100 sq. ft. for material would be $4.35 or 55 cents less than the materials required for the cement floor. The cost for the labor for the cement floor would be greater than the cost of the labor for the wood floor, but the difference need not be as great as to double the cost of the wood floor.

In fig. 4, I have illustrated how cement gutter and cement mangers might be made and then crushed rock used for the alley ways and for the platforms upon which the cows stand. The material being put in and thoroughly tamped making essentially the same sort of foundation as used for the macadam roads; after the crushed rock has been put in place and thoroughly tamped, a surface dressing of screenings or fine sand would be applied and worked in between the crushed rock by sweeping, wetting and tamping, thus forming a surface like the road bed. Such a floor as this would be very durable and would not be quite as expensive as the all cement floor. But it would not be as easy to keep it perfectly sweet and clean as the all cement floor.

Mr. Taylor—I have seen barns where they seem to think that they must have a foot of broken stone.

Prof. King—This depth is hardly necessary where simply the weight of the cows is to come upon the floor. If a team was to be driven behind the cattle in cleaning, it would be desirable to make the driveway not less than six inches thick.

A member—Would not gravel work as well as crushed rock?

Prof. King—Coarse gravel may be used in all cement floors but where it is to be finished without cement the rounded gravel stones do not bind as well as the angular pieces do.

Chairman—We simply tamp down sand, wet it and tamp it rough and build the cement walk on top of it.

Prof. King—That is right, there should be a layer of sand on the ground upon which the cement is first placed.

A member—How deep are the gutters behind the cows?

Prof. King—I like them best a little more than 6 inches, 7 or 8, and would not make the gutter narrower than 18 inches.

Question—How is the manger, is the top level with the feeding floor?

Prof. King—No. The bottom of the manger should be 2 or 3 inches higher than the platform the cows stand upon.

Question—Is half an inch of surfacing enough?

Prof. King—It will do if it is made of good Portland cement, and properly put on.

Chairman—And you do not have a cheap mason, the owner of the building is generally the best mason around.

A member—Is there any objection to ventilating a dwelling house in the same way that you ventilate a barn?

Prof. King—The ventilation of a dwelling house should be on exactly the same principle as that described for the stable, except that where you have a system of steam heating with radiators about the sides of the room. In this case the cold air is brought in directly upon the radiators so as to warm it at once before it passes into the room.

Why the Babcock Test was Discarded.

A Retreat Based Upon Incorrect Information.

(Some time since we noticed in a floating newspaper clipping, that the Babcock test had been "voted out" of a cheese factory in Pennsylvania, and, therefore, wrote to one of the parties for a statement of the reasons leading to such action. Following is the reply received:)

Ed. Hoard's Dairyman:—Yours received, and in reply will say that we consider the Babcock test a butter test, rather than a cheese test, and in a community where milk from thoroughbred Jersey and Holstein dairies are sent to the same factory, I think the Jersey men receive more than their share of the money, in accordance to the amount of casein in the milk. If all dairymen patronizing the factory, kept the same breed of cows, I think the test would be more appropriate. I don't consider the Jerseys a profitable cheese cow. The test was voted out of several factories in this locality, this spring. T. W. McClelland.

Espyville, Pa.

History records that in one of the battles of the civil war, a northern army was demoralized, and retreated, upon discovery that the enemy was provided with an unexpected supply of what appeared to be artillery. This was in the early days of that conflict, before the soldiers in either army, or their commanding officers, had learned to distinguish between the actual and the apparent. In the instance referred to, the attacking force did not wait to see the guns fired, or learn what execution they were capable of accomplishing, but fled in dismay from what was afterwards learned to be only "Quaker" guns—mere logs of wood, fashioned into the semblance of deadly cannon.

It is somewhat so, we fear, with our friends in Pennsylvania, who have resolved to discontinue the use of the Babcock test at the cheese factory. While it is true, that 100 pounds of 6% milk will not make as many pounds of cheese as 200 pounds of 3% milk, it is equally true that 100 pounds of 3% milk will not make as much cheese, or cheese of as good quality, as an equal amount of 6% milk. In other words, it has been demonstrated over and over again, that the richer the milk the more cheese it will make, and for occular demonstrations of this fact see page 194 of the current volume of Hoard's Dairyman.

It is admitted that this increase in yield does not exactly follow the increase of the fat in the milk, but what is lacking in this respect is abundantly compensated for, in the improvement in the quality of the cheese which results from mixing the rich milk with that containing less than 4% of fat, and the larger price obtained for the better cheese.

To dispute with these facts is to show contempt for the truth, and to be frightened and give up the Babcock test, because it does

"A Word to the Wise is Sufficient."

But some stubborn people wait until "down sick" before trying to ward off illness or cure it. The wise recognize in the word "Hood's" assurance of health.

For all blood troubles, scrofula, pimples, as well as diseases of the kidneys, liver and bowels, Hood's Sarsaparilla is the effective and faultless cure.

Poor Blood—"The doctor said there were not seven drops of good blood in my body. Hood's Sarsaparilla built me up and made me strong and well." Susie E. Brown, 16 Astor Hill, Lynn, Mass.

Dyspepsia—"We all use Hood's Sarsaparilla. It cured my brother-in-law and myself of dyspepsia. I owe my life to it." M. H. Kirk, 607 Franklin St., Philadelphia.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Not a Preservative but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION MILK COOLER-AERATOR. It does its work perfectly and its use doesn't violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

not give the amount of casein, is very like running away from a Quaker gun.

Jersey cows that yield 5,000 to 10,000 pounds of milk in twelve months, make profitable cows for cheese, greatly surpassing, in this respect, the average cow.

Feeding Melons.—Bloat.—Castor Oil for Warts.

ED. HOARD'S DAIRYMAN:—I should like to ask you the feeding value of citrons and pie melons for cows. We can raise them here in great quantities without much expense; in fact they grow along the roadside, and almost anywhere that the seed gets scattered. They will keep all winter, and all kinds of stock eat them almost as readily as they will pumpkins.

Would they furnish part of the succulence lacking in alfalfa hay?

Our main feed here is alfalfa; the hay is usually worth from $3.00 to $5.00 per ton, but corn is worth a cent a pound and upwards, and all other grain in proportion, so we can't feed much grain.

I see some inquiry in the DAIRYMAN about bloat; we have considerable trouble with it here, especially in the spring. There are several remedies, such as tying a stick in the mouth, etc., but the only *cure* is to stick them.

If a cow is not very bad and she begins belching, she will probably soon be all right, but if the gas forms faster than she belches it up, it is very apt to kill her, and a cow will die in a few minutes after she begins to puff up, if it is a bad case.

I have directions from a veterinary surgeon about sticking them, as follows: "In the use of the trocar to take off the gas when a cow is bloated, you should strike midway between the last rib and the pin bone, and the same distance from the transverse processes of the lumbar vertebrae and on the *left side*".

But if you (like myself) don't know where the "transverse processes of the lumbar vertebrae" are, and you find one of your cows out in the field badly bloated, and you have not got a trocar about your old clothes, just measure a span from end of thumb to end of little finger forward from the hip bone, and about the same distance down from top of spine and stick in your jack knife and in a few minutes she will be all right, but be sure to get below the bone on the back. I have had to stick several of mine lately, and if stuck in the right place it will not hurt them at all.

I want to say one word more about the castor oil remedy for warty teats mentioned in the last DAIRYMAN. I have used it a number of times and have never known it to fail if persevered with, and it doesn't make the teat sore. E. S. H.

Tulare Co., Cal.

There is no doubt that melons, such as our correspondent describes, can be given as a valuable adjunct to dry feed. It must be remembered that their nutritive value is very small. Some varieties contain not over 12% of solids and less than 0.5% of protein, consequently their feeding value would come from their use as a succulent food rather than from any actual nutrients which they might be supposed to contain.

Morals and Moralizing From Maryland.

ED. HOARD'S DAIRYMAN:—A few days ago I came across the "butter book" I kept when we ran a dairy for revenue only, and made it a business rather than a side show. During the month of January, in '92, I made ninety-two pounds of butter from eight cows; for the same month the next year, with the same number of cows, I made one hundred and ninety-eight pounds of butter. The difference is explained by the fact that the first year the hired man fed the cows and the second year I fed them myself.

In the morning before breakfast the cows had their breakfast, and during the whole day, more or less, I had the cows on my mind. And the hired man knew that fact too. It was not safe for him to slight any part of his work, for he knew that what I did not do myself I saw that someone else did. It took a great deal of time.

Twice a week I churned and printed the butter and that took nearly a half day each time, and once a week I took the butter to Baltimore, which took another half day. The milk had to be skimmed twice a day, and all the feed was mixed by me, so there was really not much time when I was not doing something or other for the cows. But then it paid. Sixty-eight pounds were sold at thirty-five cents a pound, and what of the balance was not used was sold at the grocer's for thirty cents, and there was also four quarts of cream at twenty cents a quart, making a total of $63.30 for eight cows for one month and a winter month at that.

Subsequently on account of trouble with milkers, we sold our herd, and the next year I began to take horses to board for the winter. There are lots of people in the city who drive in summer, but in winter find it too cold and then put their horse on some farm, and the ice companies have some horses that they have no use for in the winter. I began with one horse, as it was all I could get, but I sent him away in good order and this year I have fifty-two, at present.

When I made the change from cows to horses, I thought it would be no work to take care of the horses after taking care of cows. But now I go down to the barn in the morning and, except for about an hour at dinner, I am there all day. But the horses pay reasonably well, too, as well as the cows, and the moral to both horses and cows, if what limited success I have met with will allow me to moralize, is, that if anything is wanted to succeed it must have constant care, and nothing will succeed without plenty of good hard work. P. B. CROSBY.

Feeding Whey at the Cheese Factory

ED. HOARD'S DAIRYMAN:—I was very much interested in the paper read by H. E. Cook, of Denmark, N. Y., at the state dairyman's convention, and published in HOARD'S DAIRYMAN May 12th, and noted carefully the part relating to the feeding of whey at the cheese factory.

While that manner of using the whey has some merits, there are some strong objections to it, especially the odor that will rise from the yard where there are many hogs, a very bad feature near a cheese factory or any other place; besides the hogs are more liable to disease than when cared for at home.

I have seen that way tried in the state of New York, thirty years ago, and there are other objections to it. Hogs require a grain ration, and most farmers prefer to feed their grain on their premises, and keep the fertility at home; besides hogs can be cared for in a far better manner than in a large herd at the factory.

Mr. Cook's way is better than feeding sour whey, but there is no necessity of having sour whey. I have been among the cheese factories some years buying cheese and furnishing factory apparatus and supplies, and am fully convinced that there is no necessity in having sour whey.

There are a few factories that are equipped to keep the whey sweet, and the owners say that the expense is fully offset by the better quality of milk received, besides the benefit to the farmer.

There is less danger from bacteria in sending sterilized whey home from the factory in the can than in receiving the milk from the farm. I would prefer to have the cans filled with sterilized whey than to have them go home empty, unless cleaned and steamed at the factory, and then treated again at home.

The expense of sterilizing the whey is not large. A good galvanized iron whey tank, the best place for it is in the boiler room, raised high enough so a pipe will discharge the whey in the can on the farmer's wagon, a steam pipe leading from the boiler to the whey tank.

In the forenoon, every day, wash and steam the tank and after forcing whey in the tank, turn on the steam and heat to 150° or 160°. In the summer season the whey will be somewhat warm in the morning, and if desired, steam may be applied a few minutes and the farmers can have warm sweet whey to haul home, and if he will take care of his storage, need not have sour whey.

A steam jet pump (the Blakeslee requires very little steam) can be used to force the whey into the tank, which will assist in raising the required temperature.

After the outfit is in, it requires a little more fuel, but less labor than should be given the old-fashioned whey tank, every day.

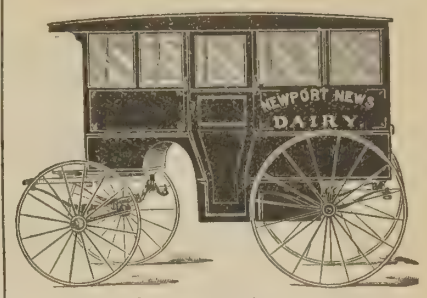
At some small factories the patrons pay the cheese maker extra for sterilizing the whey, where a large amount of milk is received the owner of the factory can afford the expense. Too many factories have a boiler that is too small, or worse, none at all.

The worst feature of the cheese industry, in this country, is, there are too many small, poorly equipped factories, whose owners cannot afford a first-class outfit, and with which a first-class man can not afford to idle away his time.

When the number of our factories is reduced one-half, and the farmers learn that they can well afford to haul their milk a mile or two farther to a factory that is equipped with a first-class and up-to-date apparatus, and where experience and brains enter into the management of the concern, then may we look for the greatest improvements in the quality of our cheese.

Outagamie Co., Wis. F. L. FORWARD.

One of the Largest Dairies in the World.

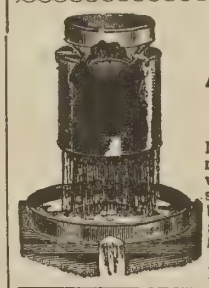


This dairy is situated about fourteen miles from Newark, New Jersey, and is owned and operated by Francis Francisco.

There are never less than one thousand cows at this establishment. The number varies from ten to twelve hundred. Mr. Francisco receives, at least, one carload of plump "new milch" cows from his Iowa ranch every week. His inspector tests and examines every cow rigidly, and every one which is found to be out of condition, or which does not give milk which, in amount or quality, equals the standard required, is converted into beef. Then the rest are given a place in the dairy. Every cow is killed and sold to the meat dealer as soon as it becomes "dry," and its place filled by a new milch cow.

These cows are kept in three large stables, and sixty men care for their wants. These stables are clean, dry and well ventilated. Every cow looks sleek enough to go to a wedding. Every cow is curried daily, and every cow's udder is thoroughly washed before each milking. The stables are lighted by electricity, and cooled by electric fans As every cow is milked, the milker pours the fluid into an automatic carrier, which takes it to the milk house, and places it in vats which are surrounded by ice. These cows are fed either ensilage or hay, and grain, every day in the year. They are kept shut up every inclement day, but every pleasant day they are let out to pasture. The entire establishment covers about three hundred acres. Not only is every cow tested when she first arrives, but frequently after that time as well, and every cow whose milk does not test, at least, 4% butter fat, or in any other way falls under the requirements, is carted away to the slaughter house, where its neighbors are destined to go in a few short months at the very most.

The milk from this establishment is bottled, and sealed, and shipped in refrigerator cars to New York city, and disposed of to the retail trade. The price received varies from season to season, but is never less than ten or more than fourteen cents a quart.



The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairymen at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

The YOUNG AERATOR And Cooler

Needs no water or ice, removes all odors and gases, warranted to keep milk sweet from 6 to 12 hours longer than any machine on the market or money refunded. Circulars free,

W. H. YOUNG,
Box 135, Aurora, Ill.

Village and Country Carpenters and Millwrights, Attention!

A thoroughly reliable manufacturing concern wants you to represent them in your vicinity, in connection with your other business A good chance. Don't wait. Address, with references.

X, Y, Z, Box 1592 Philadelphia, Pa.

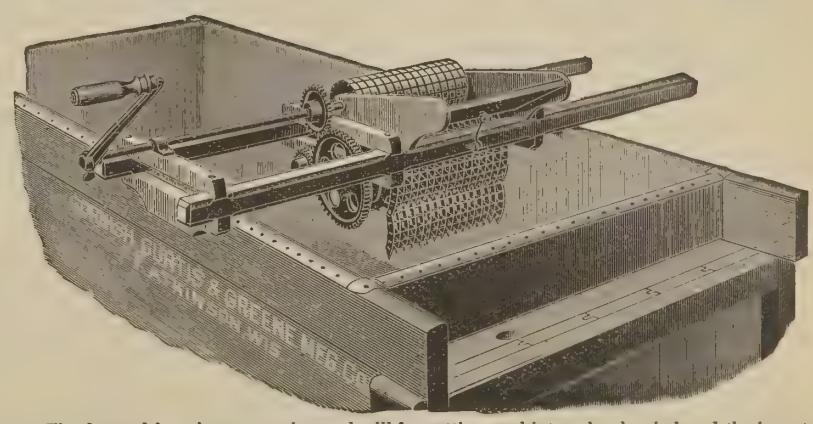
KILFLY.

A harmless liquid applied to cows with a CHILDS ELECTRIC SPRAYER, that protects them from flies, increasing the amount of milk, making comfort for cows and milkers. Sample lot—One gallon can Kilfly and one Sprayer, securely packed, expressed to any address (except in State of Maine), charges prepaid, upon receipt of $2.00. Special prices for quantity. AGENTS WANTED EVERYWHERE.

CHARLES H. CHILDS & CO., Utica, N. Y.

BUY "DIRECT FROM FACTORY" BEST
MIXED PAINTS

At **WHOLESALE PRICES**, delivered **FREE** For Houses, Barns, Roofs, all colors, and save dealers profits. In use 54 yrs. Endorsed by Grange & Farmers' Alliance. Low prices will surprise you. Write for samples. O. W. Ingersoll, 267 Plymouth St., Brooklyn, N.Y.



GEM FULL CIRCLE Baler

Warranted the lightest, strongest, cheapest & fastest Full Circle Baler in the market. Made of wrought steel. Can be operated with one or two horses. Will bale 10 to 15 tons of hay a day. Write for description and prices.

GEORGE ERTEL CO., QUINCY, ILL.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentations to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00.**

CORNISH, CURTIS & GREENE MFG. CO., Fort Atkinson, Wis.

Inventors, Manufacturers and Dealers in Everything Pertaining to Butter and Cheese Making.

Agents for DE LAVAL ALPHA SEPARATORS.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, XV.

GLOSSARY.

Disinfection—To remove or destroy infection, a process that kills disease germs.
Antiseptic—An agent that checks or stops bacterial growth without necessarily destroying it.
Mercuric bi chloride—Same as corrosive sublimate; one of the strongest of germ destroying agents.
Milk of lime—A thin whitewash made from unslacked lime and water
Formalin—A liquid frequently sold under a variety of names, as formol, formalose, etc., which contains in solution about 40% of formic aldehyde, a powerful gaseous disinfectant.

CONTROLLING DISEASE BY DISINFECTION.

Another method of controlling disease, aside from that of preventive inoculation, is to use such measures as will destroy disease bacteria, and thus render it impossible for animals to contract contagion. This is done by disinfection, which is accomplished by the destruction of bacterial life by either chemical or physical agents. All life, animal or vegetable, is killed by the application of high heat, or by the effect of many different chemical substances. Unfortunately, what will destroy bacterial life also affects prejudicially the tissues of most of the higher animals and plants. It is therefore impossible to disinfect the living animal by the application of germ destroying forces to the tissues. But it is possible to kill this germ life, if it can be caught outside of the animal.

Remembering the fact that disease is contracted by the absorption of disease germs from without, it is often possible to destroy these organisms, while they are outside of the body, and thus prevent contagion from spreading.

It would of course be impracticable to do this over large areas, as fields or pastures. In fact, it is not necessary to treat these areas in this way, for it must be remembered that disease germs are not universally distributed in nature, but are confined generally to localized places, as stables, barns, portions of single fields or pens.

Many different methods have been devised that accomplish the desired end, i. e., the destruction of infectious organisms. Which of these will be used in the individual cases that come up for treatment will depend upon a number of factors. First of all, emphasis should be laid upon the question of efficiency. Concerning this, there is need of much change in popular opinion. The public at large have very imperfect and often erroneous ideas in regard to the matter of disinfection. Very frequently removal of an odor is regarded as equivalent to disinfection, particularly if the odor is a putrid one. Not infrequently chemical substances are powerful deodorizers, but have little germ destroying power. Then again, many chemicals check the growth of bacteria, or even inhibit their development when used in sufficient quantities, but do not destroy the same. Such substances are known as antiseptics, in contradistinction to disinfectants, which actually destroy bacterial life. The so-called preservatives that are used illegally as food preservatives, belong as a rule to the antiseptic and not to the disinfecting class. Even disinfectants like formalin are not infrequently used as antiseptics, by employing a very dilute solution.

Now it is manifestly out of the question to expect to destroy contagious matter, where these mild antiseptics are used. The germ life may be held in abeyance, so far as its growth is concerned, but it is not killed, and until it is actually destroyed, danger, of course, exists.

Again, the public are apt to put their faith in many compounds, or substances that have really a low disinfecting power, or the efficiency of which is subject to modification in various ways. Such, for instance, is the case with sulphur. This agent has been used for many years, and in the eyes of the public is still regarded as a most satisfactory disinfectant. When used under proper conditions, its efficiency cannot be questioned, but as it is ordinarily employed, its value as a germ killing agent is very slight. The usual method that is generally followed, where a few ounces of sulphur are burnt over a shovelful of coals, does practically nothing, except to put the mind of the operator at ease. Disease germs are able to stand such treatment with impunity. If, however, sulphur is used under proper conditions, in a room that is tight enough to hold the gas, it is possible to kill most bacteria by a thorough treatment. Three pounds should be employed for every 1,000 cubic feet (ten feet square and ten feet high,) and then the gas should be generated in contact with moisture. Dry sulphur fumes are relatively harmless, but in the presence of moisture, this gas unites with water, forming the deadly sulfurous acid, which is a most powerful disinfectant.

Another fallacy often noted in the use of disinfectants is the matter of contact with disease matter. To kill disease producing bacteria, or any other, requires actual contact of the disinfectant with the disease germ. The destruction of the life of the organism is not infrequently produced by the chemical union that takes place between the protoplasm of the germ and the disinfectant. This chemical union cannot occur at arm's length; even the effect of physiological poisons is not worked unless there is intimate contact. It is therefore necessary to bring the disinfectant into *immediate and complete* contact with the germ life to be destroyed. In the case of a gaseous disinfectant this is relatively easy, for its penetrability is, of course, much greater than that of a liquid, but even where gases are used, care should be taken to remove overlying dirt and matter, so that the disinfectant may penetrate all the cracks and crevices possible. It is, therefore, necessary to clean out all refuse, litter, etc., especially in barns before disinfection is carried out.

Not only may it be impossible for the disinfectant to reach the disease organisms through the accumulation of dirt, etc., but the power of some disinfectants is greatly reduced by applying them where dirt and foreign matter is present. Take corrosive sublimate, which is one of our most powerful germicides, but when it is used where it comes in contact with proteid or albuminous material, it very readily unites with albumen and so its disinfecting action is spent upon inert material, and not upon the deadly germ life.

Such facts as these make it necessary that any disinfectant that is used be chosen with due regard to its efficiency under varying conditions. Under some circumstances one disinfectant has a great advantage over another, sometimes in efficiency, sometimes in cheapness or in some other way.

Space does not permit of a full discussion of the matter of disinfectants, and in this connection, it will only be possible to give some of the standard methods that are the most available for general purposes.

For pens and small areas, fresh lime is very satisfactory, but this should not be used until all refuse is first removed. A thin whitewash prepared from freshly slacked lime (so called milk of lime) is regarded as one of the best disinfectants. In the treatment of fecal discharges this cheap substance is often given preference. The process of frequently whitewashing barns and stables is also a good one to recommend, on general principles. Not only does it absorb odors, but it reflects all light and thus intensifies the illumination that ordinarily is below what it ought to be. To secure the disinfecting action of whitewash, it is necessary to use unslacked lime. Air slacked lime has no value for this purpose. The relative inexpensiveness of this material makes it especially desirable where considerable surfaces are to be treated.

Corrosive sublimate or mercuric bi-chloride (1 part to 1,000 parts of water by weight) is also a standard disinfectant, but sublimate solution is a strong poison, and besides it corrodes metal surfaces. Its use in barn disinfection is somewhat limited on account of these factors. Carbolic acid and the many compounds that have been derived from the same, hold a popular position among the disinfectants.

These substances are powerful in their action (5% solution in water is as strong as is needed) but the odor and strong poisonous properties are somewhat objectionable, and the readiness with which they unite with albuminous substances minimizes their value for farm purposes.

One of the most promising disinfectants that has come to light in recent years, has been formalin. This disinfectant possesses the advantage of being applicable in both liquid or gaseous condition. Formalin is a watery solution of the gas known as formaldehyde. A saturated solution contains about 40% of this gas. When used as a liquid disinfectant, it is diluted to about 1 to 2% of formalin. In such strength disease bacteria are killed in a few minutes.

Where the rooms are capable of being tightly closed, it is possible to use it as a gas. This method is not so applicable to barn disinfection, because it is generally difficult to render the room perfectly tight. To secure best results as a gas, the surface should be damp. The gas formaldehyde may be generated in a variety of ways. It may be formed by burning wood alcohol in a lamp that does not permit of complete combustion, or formalin itself may be distilled and the gas given off in this way. One of the most efficient methods of those that can be utilized without the use of special apparatus is the sheet method. Saturate an ordinary cotton sheet with formalin, diluted with several volumes of water. About 5 ounces of formalin should be used for every thousand cubic feet. Hang this up in the room. A sufficient number of sheets should be used to give the necessery surface exposure. The formalin evaporates quickly, giving off the pungent formaldehyde gas. This is irritating to the mucuous membranes (eyes, nose and throat) of a person, but not poisonous. The room should then be kept tightly closed for a period of at least five hours. Such a treatment can be readily used by anyone, and its efficiency is quite complete. One of the great advantages of formalin is that it does not injure the color of even fine and delicate fabrics. Of course this is of no particular consequence in farm disinfection, but in disinfecting a room in a house, it is often of great importance to be able to treat hangings, beddings and clothing. Sulphur ruins most of these fabrics.

In speaking of disinfection and measures used to accomplish this end, mention must also be made of steam and hot water. If the temperature of any surface is raised to approximately the boiling point, all germ life, in a vegetating state, will be killed. It is thus possible to destroy disease bacteria that are unable to form spores, by the use of these agents. As a rule, however, the chemical methods of treatment will be more applicable.

Does It Pay to Use Commercial Fertilizers?

Ed. Hoard's Dairyman:—If it pays to grow a crop at all it pays to use commercial fertilizer on it, provided the soil is not already rich enough, or we lack the necessary animal manures for fertilizing the piece. In other words, it does not pay to work poor soil. It requires no thought to say that it does not pay to use fertilizers on potatoes when the crop sells for 10 cents per bushel, but we cannot tell when we plant a piece to potatoes, what those potatoes will bring.

If we sometimes knew, it would be well not to plant them at all. But as we do not know, it is best to plant enough for home use anyway, and these ought to be well fertilized that the tubers will be large and smooth and the crop worth the labor of planting and caring for. Even though we could sometimes buy potatoes in the market as low as it costs to produce them, it is best not to run the risk, and anyway, potatoes grown at home are better, because not exposed and bruised so much by handling.

One factor that farmers do not consider in the cost of fertilizing for a crop, is that while home-made fertilizers, like barn manure, appear not to cost anything in dollars and cents, they really do cost as much per pound of the essential elements as concentrated fertilizers do, and when used on a crop ought to be reckoned.

If we buy grain and feed it to our animals and apply the manure to our crops we ought not to think that we are getting the manure for nothing. The cows and horses have manufactured it and ought to get some of the credit of it. This feeding of grains is a commendable practice and ought to be more encouraged among farmers, but let no farmer suppose that he can feed worthless food to animals and expect to get from them valuable manure. Poor hay fed to animals produces poor manure worth little more than the hauling. It is only when rich grains and the better qualities of hay are fed that the manures are rich in fertility.

Keeping the thought in mind that farmers rarely credit manures, made on the farm, with any particular value, we notice that when they apply this kind of manure to a piece of land they put it on very liberally. Now it is no uncommon thing to see 40 loads of manure drawn on to an acre of land for the corn crop. Now this manure cannot be made and applied to the land provided it is rich grain fed manure for less than $2.00 per load. This costs the farmer in reality $80 00 for fertilizing the acre. Now what farmer would think of applying $80 00 worth of commercial fertilizers to an acre of land for the corn crop?

Does anyone doubt if a farmer did this that he would be bountifully repaid with a good crop, in fact, a more satisfactory crop than that produced from the acre fed with animal manure? This is not said to encourage farmers not to feed grains and make more manure, but to show them that any manure is worth just what it actually benefits a crop.

A common mistake among farmers is to apply a very small amount of commercial fertilizers to an acre of land and expect good results. The average man who would apply 40 loads of cow manure to an acre would expect equally as good results with the application of 200 pounds of concentrated fertilizers. Of course he would be disappointed, for this amount of fertilizers, while it is beneficial to start the crop and get it going so its roots can reach manure below, is utterly inefficient to carry the crop through to maturity.

There are some crops that it will pay to apply a small quantity of fertilizers to and the results will be beneficial, usually in proportion to the amount of fertilizers used, but it rarely pays to use commercial fertilizers in very small quantities on the corn crop, except as there are animal manures also used to carry the crop through the season. A good rule to go by in figuring whether it will pay to use commercial fertilizers is to first see whether the crop is worth, even though it be a good one, the cost of fertilizers. Of course, in this calculation, it is fair to estimate the value to other crops to follow and the permanent value rendered the soil.

It is quite safe to say that the crops of potatoes, small fruits and buckwheat are always better and repay any expense incurred in the purchase of commercial fertilizers. The use of seventy-five to one hundred pounds of commercial mixed fertilizers on an acre of buckwheat will increase the growth of straw so that the reaper will pick it all up when the crop is cut and increase the crop of grain four-fold. When used on any crop, a well mixed commercial fertilizer containing a good proportion of potash will increase the grain yield wonderfully. This is especially true when used in conjunction with animal manures.

I think a good plan is to plow under a coat of barn manure for the corn crop and put 200 to 300 pounds of commercial manure in the drills. This not only starts the corn nicely and carries it along till it reaches the manure below, but also tends to keep the wire worms away, a point which is very important. The crop of potatoes in our section is always very much larger in yield and in single specimens, the tubers are smooth and free from scab, when a good application of special potato manure rich in potash is used. On good strong soil in these parts the application of 400 to 700 pounds of potato fertilizer more than doubles the total crop and increases the quantity of merchantable tubers four-fold.

A common mistake of farmers is that they are purchasing the poorer grades of fertilizers instead of the higher grades. Manufacturers are putting these out in large quantities at the present time and this is a result of the demand for something cheap. As the filling of cheap fertilizers is worth no more than the earth around our farms, I do not see where farmers gain in paying freight and sacking expenses on something that can be gotten for the asking at home. Farmers should buy the higher grades of fertilizers only and no matter what agents or others tell you, a ton of actual value $40 00 fertilizer is more profitable for you to buy than two tons of fertilizer that has an actual value

of $20.00 per ton. Do not be deceived. Study the analyses closely and buy the higher grades. L. J. F.
Pulaski, N. Y.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The aggregate offering of butter on Monday's Elgin Board of Trade was 34,380 pounds. A bid of 16 cents was made for the entire offering, but only 7,320 pounds were sold at this figure, other manufacturers declining to sell at this price. The Quotation Committee announced the market easy at seventeen cents. The sales reported were:

Factory.	Pounds.	Price.
Shannon	1,560	16c
Elkhorn	1,560	16c
Baileyville	1,380	16c
Winslow	1,740	16c
Florence	1,080	16c
Total	7,320	

The markets for the corresponding week of the three preceding years were as follows:

May 23, '98....22,200 lbs. of butter sold at 15½c
May 24, '97....44,400 " " " 15c
May 25, '96....83,820 " " " 15@16c

The New York market Monday was reported steady at 18 cents. H. C. B.
Elgin, Ill., May 22.

Concerning Florida Butter.

ED. HOARD'S DAIRYMAN:—Seeing a letter in your valuable paper from a would-be dairyman, of Florida, saying he cannot make butter that will keep a week or longer. I don't know what part of Florida he is in, but I can assure him, if he will come up in the dairy district of Florida, he will see butter one month old as fresh as just churned. If he wants to go into the dairy business for butter making and will write to me, I may be able to give him some points to his advantage. I can make as good and sweet butter here in Florida as I ever made north, and it will keep as long. I can assure our friend it is not the climate, but must be some local trouble.

I could not run a dairy without your paper. I keep every number, and refer to them often, and especially if I run against a snag, and then I can always find a way to pull by and avoid it next time. Thanks for the best dairy paper printed. TRYPHOSA.
Florida.

Warm vs. Cold Water for Washing Butter.

ED. HOARD'S DAIRYMAN:—I think Mr. Rockwood makes a mistake in advocating the warm water for beginners. He says he has made butter this way for over a year. I have made it that way for ten years, and some years made as high as 23,000 lbs.

I have tried the warm and cold water both, and I know the beginner will have better success with cold water, for this reason: this butter will be solid and in packing he can work out the brine far better than he can in soft butter. In washing with the warm water the granules will pack too soon when salted, and the butter being soft will retain a much larger portion of water. His theory of salting and gathering is correct, but the beginner will have far better success with cold water. After it is thoroughly worked in the churn, the secret of success in packing is a good packer and elbow grease, as they used to tell us when we were children.

FARMER'S WIFE.

DAIRY MARKETS.

ELGIN, Ill., May 22—Butter—Easy at 17c; offerings 573 tubs; sales 122 tubs at 16c. There were bids of 16c on all lots offered.

CHICAGO, Ill.. May 22—Butter—Creamery, extra 17½c; firsts, creameries, 16½@17c; seconds, 13½@14c; dairies, selections, 15@16c; extra ladles 12½c; packing stock, fresh, 10@10½c.

Eggs—Fresh, at mark, cases included, sold at 12¼@12½c; cases returned, 13c; Duck eggs 12@12½c; Goose eggs, 15c.

Cheese—Full cream, Twins, new, good to choice, 9@9½c; Young Americas, 10¼@10½c; Swiss, 10½@13c; Limburger, 7@9c; Bricks, new, 7½@7¾c

Cattle—The cattle market opened slow, with buyers and sellers apart in their views. Opening bids were generally 10@15c lower than the close of last week.

A load of 1,460-lb Polled Angus steers sold at $5.65, or 15c above the top last week, and 15c above the top a year ago but they were better than any cattle sold here last week. Two loads of 1,650 lb fed Western steers sold at $5.55, being the highest branded cattle sold here this month. The next highest was $5.50. Most of the native beef cattle sold at $4.85@5.25; fed Westerns principally at $5@5.15; Missouri Texas, 1,020@1,160 lbs, $4.60@4.85; straight Texas steers, 1,027@1,202 lbs, $4.70@4.90; Texas stags, 1,218 lbs, $3.80; native cows, $2.25@4.65; heifers, $3.40@5; stags, $4.10@4.90; calves, $4@7; feeding cattle, $4@5.10.

Bran—Firm and quotable at $10.50 per ton.

MILWAUKEE, Wis.. May 22—Butter—Creamery, fancy prints, per lb, 17½c; extras, per lb., 17½c; firsts, per lb., 16@17c; seconds, per lb., 14@15c; imitations, per lb., 14@15c. Dairy, selections, per lb., 13@15c. Roll, fair to choice, fresh, 9½@10c; packing stock, 9½@10c, grease, per lb., 4@6c; whey, per lb., 7½@8c. Market tending downward, with receipts of 17,510 lbs., and a fair local and outside demand.

Cheese—American full cream—new, choice to fancy, 9@9½c; Brick, new, per lb. choice 7½@8c; Limburger, Fall, choice, per lb, 9@9½c; new choice, per lb, 7½@8c. Swiss—Drum, choice, 12½@13c; Block, choice 10½@11c. Considerable inferior new offering which has no quotable value. New, easy with receipts of 10,260 lbs, trade being moderate.

Eggs—Fresh, per doz, 12c, cases returned. Market slightly higher, though receipts are 1,187 cases, the bulk of which go into storage while local wants are fair.

FOND DU LAC, Wis., May 22 –Cheese—Offerings 500 Twins and 104 Daisies; market quiet at 8¾c for Twins.

b SHEBOYGAN, Wis., May 17—There were 880 aoxes of cheese offered on the call board to day, nd all but 35 cases of Young Americas and 40 cases of Longhorns were sold as follows: 126 Twins and 60 Daisies at 9c; 330 cases Young Americas, at 9⅝c; 235 cases at 9½c.

SHEBOYGAN FALLS, Wis , May 17—The sales reported to-day were 300 boxes Twins, at 9c and 300 cases Young Americas, at 9¾c.

MANITOWOC, Wis., May 17—Offers of cheese on the Dairy Board to-day were 150 boxes Daisies, 100 Twins, 300 Young Americas. Daisies and Twins sold at 9c: 175 Young Americas, at 9¼c and 125 at 9¾c.

NEW YORK, May 22—Butter—Creamery, Western, extras, 18c; firsts, 17@17½c; state extras, 18c; firsts, 17c@17½c.

Cheese—State, new full cream, large colored or white choice 9¾c; old choice, 11@11¼c.

Eggs—State, Pennsylvania and Western, 13½@14½c.

PHILADELPHIA, Pa., May 22,—Butter—Solid-packed separator creamery, extras, 18¼c; firsts, 18c; seconds, 17c; imitation creamery, extras, 16c; firsts. 15c; seconds, 13c; ladlepacked, extras, 15c, firsts, 14c; seconds, 13c. Print butter: Creamery, extra, 20c; first, 19c; seconds, 16@18c.

Eggs—Pennsylvania and nearby, 14½c; Western, 14½c; Southern, 13½@14c; Southwestern, 14c;

ST. LOUIS, Mo., May 22—Butter—Lower; creamery, 15@19c; dairy, 12@15c.

Eggs—Firm at 11c; loss off.

CINCINNATI, O., May 22,—Butter—Steady.

Eggs—Firm, higher; 11¼c.

Cheese—Steady; good to prime Ohio flat, 10c.

NEW YORK MARKET.

NEW YORK, May 20—Butter—Receipts for the week, 44,112 packages. Exports for the week, 200 packages. The season has been cold and backward and this spring make of butter shows less life and flavor than it should. The herbage of the country hath in it just now an amplitude of dandelions which imparts to butter a golden color. Buyers are close in selecting, but high flavored butter is so difficult of production that their choice is limited and the fancies sell quickly, This bids up top quotations higher than the bulk creameries can be sold at, and makes a dragging market Quite a portion of the receipts were put into freezers or carried over unsold. Prices are starting into grass makes at rather above the average of the World's markets and at 5 to 10% higher than a year ago. We quote:

Creamery, extra 18c, medium 16½@17¼c, poor 15@16c; Dairy, extra 17@17¼c, medium 15@16c, poor 12@14c.

Cheese—Receipts for the week, 18,193 boxes; exports for the week 3,216 boxes. There was a fair demand early in the week from all quarters at full prices. White cheese were very scarce and sold ½ cent a pound higher than colored. Exporters paid 9@9¼c for large colored, and up to 5⅝@9¾ cents for few parcels of white cheese. Home trade were free buyers of small colored at 9¼@9½c; white cheese were hard to find and some sales were reported at 10@10¼c. At the close there is more stock offering, prices are lower and unsteady. Sales yesterday at Catteraugus were, large 8½c, and small 9c. We quote:

Full Cream (small) extra 9@9¼c, medium 8@8½c, poor 6@7c; Full Cream, (large) extra 9@9¼c, medium 8@8¼c, poor 6@7c; Part skimmed, extra 7¾@8c, medium 6@6¼c, poor 4@5c

Eggs—Receipts for the week, 85,006 cases. Arrivals continue liberal, but a strong steady demand all the week kept stock well cleaned up and at the close prices are advanced 1c a dozen. We quote:

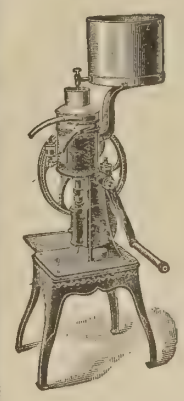
New York & Pennsylvania, per dozen, 15@15½c; Western & Northern, freezer pack, per dozen, 14½@15c, All other sections, 12@14c.

177 Chambers St. DAVID W. LEWIS & Co.

FOREIGN MARKETS.

BOSTON, May 20—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as steady and it is thought that prices have touched bottom on finest grades. Finest Danish is selling at 20@20½c, with fine at 19@19¼c. Irish creameries 19@20c, with very good offerings at 18@18½c. Some fine fresh Canadian creameries in boxes have sold as high as 19c in some markets, while in others they have only brought 18@18½c. Little or no American butter offering Some ladles that are held at 14c are meeting a poor sale. 13c is about as much as buyers care to pay as there is such good value to be had in fresh made Dutch and low grades of Irish at 15c it is taken in preference by buyers. The outlook for low grades of butter for the next six weeks is very poor.

Cheese markets are somewhat steadier this week but the tendency is downwards. Old is getting into small compass but the price restricts consumption. New cheese is dropping but arrivals, so far, have sold readily at 10@10½c.



BALTIMORE, Md., May 22, Butter—Market steady: creamery, separator, extras, 20c; extra firsts, 18@19c; creamery, firsts, 17@18c; creamery imitation extras, 15@16c; ladle, extras, 14@15c; Western storepacked, 11@13c.

Eggs—Market firm; strictly fresh stock, 12½@13c.

BALTIMORE MARKET.

BALTIMORE Md., May 18th—The continued light receipts of separator creamery butter, from regularly contributing points, has had the effect of infusing considerable life into the trade again this week, and the liveliness has been increased and intensified by the advance in prices noted at other cities, the impression having become general, very early in the week, that this market would be compelled to follow the others if we expected to hold our own in the competition for the commission trade that seek to dispose of their product in the flush of the early grass make.

Multiplied Value In CREAM SEPARATORS

DE LAVAL CREAM SEPARATORS are twice as well made and cost twice as much to make as imitating machines. They run with half the power, half the speed and half the wear, require but half the care and last twice as long as other separators. Under harder conditions their work is doubly efficient, *and under all conditions they save twice as much as other separators over setting systems.* Their sales are ten times those of all other machines combined. Their price is no greater but on the contrary less than cheaply made imitating machines in proportion to actual capacity, regardless of overwhelming superiority in every feature of separator efficiency.

Send for new 1899 catalogue.

THE DE LAVAL SEPARATOR CO.

Western Offices: RANDOLPH & CANAL STS. CHICAGO.
GENERAL OFFICES: 74 CORTLANDT STREET, NEW YORK.
Branch Offices: 1102 ARCH STREET, PHILADELPHIA.

This advance has to it every symptom of midsummer madness, and to the indifferent spectator the effect is forseen as clearly as though it were an accomplished fact. Before this advance, the prices for creamery butter were too high to attract orders from England and the continent of Europe, and now we proclaim to the world that we do not want their trade, when the truth is that America cannot consume the output of creamery butter at remunerative figures, and when exporters will not take the surplus, it acts like a damper to deaden the movements throughout the season. Imitation creamery and ladles are arriving in larger quantities, but far from being sufficient to meet the city demand. Some few rolls are being received and as shipments of this variety are not encouraged at this time, on account of the approaching warm weather, it is presumed that hereafter rolls will be turned into solid packed.

Butter—Creamery Separator—Extras, 19@20c, firsts, 18c; seconds, 17c; creamery gathered cream, extras, 18c; firsts, 17c; seconds, 16; creamery Ohio, extras, 18c; firsts, 17c; seconds, 16c; Iowa & N. W. Ladle, extras, 15c; firsts, 14c; seconds, 12@13c; Ohio & Indiana Ladle, extras, 15c; firsts, 14c; seconds, 12@13c; Roll, extras, 13c; firsts, 12c, seconds, 11c; Storepacked, extras, 13c; firsts, 12c, seconds, 11c; creamery blocks. (2 lb), extras, 21c; firsts, 19c, seconds, 18c; creamery prints. (½lb), extras, 21c, firsts, 20c; seconds, 19c; Md, Va. & Penna. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Eggs—The receipt of eggs while on the liberal order, have not been in excess of the demand; all receipts have been promptly placed on arrival, and still the cry is for more; so we advise you to let your eggs come right along as we are in a position to handle them; market firm at 12½c. HALT—This means for you to be so kind as to pack your eggs in cases, and not in barrels or boxes; they not only sell better in cases, but the loss is not one-fifth what it is in barrels and boxes, as so few know how to properly pack eggs in these kind of packages.

Cheese—Receipts of choice old cheese continue light; the demand is fair; some few lots of new cheese have made their appearance; the quality is not up to the standard as yet; our quotations are for good to fancy old cheese. N. Y. State—Cheddars, fine, 11½@12c; choice, 11c; fair, 9@10c., c; Flats, fine, 12@12½c; choice, 11¼@11¾c; fair, 9@10c: Small, fine, 12¼@12¾c; choice, 12@12½c; fair 9½@10c; Ohio flats, fine 11@11½c; choice, 12@@11c: fair, 8½@9c; Ohio Picnic, 11½@12c; choice, 10@11c; fair, 9½@10c; Swiss Cheese, fine, 11@12c; choice, 10c; fair. 8½@9c.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—"Reta's Parole," 20 months' old, solid color, and standard bred. Fine individual and well behaved. Direct blood of best St. Lamberts and Combination. F. L. GASTON, Normal, Ill. 12-tf

For Sale—Fifteen h. p. boiler and 15 h. p. upright high speed engine nearly new, also 6 h. p. engine. GEO. WOODRUFF, Adm'r, Janesville, Wis. 14-4

Scour Cure—Stops scours in calves. Large bottle $1.00. A. S. ALEXANDER, V. S., Evanston, Ill. 15-tf

Wanted—A buttermaker to take care of from 2,000 to 5,000 lbs. of milk daily, under my supervision. Please give length of experience and salary wanted to M. H. TEILMANN, Little Sioux, Iowa.

Wanted—Position at once as manager or working foreman of good dairy farm. Thoroughly understands dairying and farm management in all its branches, such as erecting and starting plants, handling all kinds of farm machinery, and especially fitted for caring for thoroughbred stock. First-class butter making a specialty. Address G. P. KNAPP, Clinton Corners, New York. 14-2

For Sale—Short-horn bull calf by Earl of Irvin No. 125805; dam, Countess Flora. Beautiful light roan, dropped Jan. 5, 1899. Price, $60.00 f. o. b. here. HENRY LACY, Syracuse, N. Y. 14-2

Wanted—Farm superintendent on dairy farm in Waupaca County. Fine house and pleasant social surroundings. Permanent position on salary. Married man, with experience. Good references required. M. C. PHILLIPS, Oshkosh, Wis. 13-4

Tamworths, ready to wean, $10 each, or $15 delivered. Hermanville Farm, P. E. I., Canada. 32-52

Wanted—A first-class man to rent a fine dairy and stock farm within three miles of the city of Janesville, Wis. H. F. KELLER, 251 South Jackson St. Janesville, Wis. 12-4

Wanted—A position in a dairy, would prefer a pasteurizing dairy. Can furnish first-class recommendations. Address C. G. MORROW, Urbana, Illinois.

Guernseys—wanted. HALL ROBERTS, Postville, Iowa, wishes to purchase four pedigreed Guernsey heifers, coming two, to drop calves during summer and fall.

Wanted—at once, a good, all round dairyman and farm hand. Must understand separator and steam power. Address "M. L.," care Hoard's Dairyman.

Excursion tickets will be sold at greatly reduced rates, from all stations, for trains arriving Chicago June 2, 3 or 5, limited to include June 13, account of meeting American Medical Association. Apply to agents Chicago & North-Western R'y. 15-2

Exceptionally Low Rates to Kansas City, Mo., via the North-Western Line. Excursion tickets will be sold at greatly reduced rates, from all stations, June 3 and 5, limited to include June 10, account of Modern Woodmen Meeting. Apply to agents Chicago & North-Western R'y.

DAIRYING IN IOWA.

The report of Dairy Commissioner Norton of Iowa, shows a marked increase in the use of farm separators, the cream alone being delivered at the creamery.

Ninety-three creameries in forty-seven counties report 904 farm separators in use. One creamery reports that all its patrons will furnish cream from farm separators. The commissioner says that an increase or decrease in the number of farm separators reported next year will indicate the degree of success in the experiment.

On the question of the matter of the price paid for making the butter at the creamery, the report shows that it is governed almost wholly by the amount of milk the patrons furnish.

Tables are given showing the average cost of making a pound of butter in creameries of different capacities. There is a decrease in cost with an increase in the amount of milk handled. The difference between the highest and the lowest averages is 1.21 cents, which is more than 11 per cent of 19.71 cents, the average price by the year, of a pound of butter. A decrease in creamery expense will be followed by an increase in the price paid farmers for butter fat. A cent a pound saved will mean nearly $1,000,000 on Iowa's entire butter product.

The creamery reporting the lowest cost per pound for butter making, is located in one of the best dairy counties of the state. This creamery made 400,000 pounds of butter during the year at a cost of one cent per pound. The largest creamery in the state operating without skim stations, manufactured 539,000 pounds of butter at a cost per pound of 1.2 cents.

In creameries receiving not more than 1,250,000 pounds of milk the cost per pound of butter making is reported from 5 to 7 cents per pound, the average being 3 cents.

In creameries receiving not more than 2,250,000 pounds of milk, cost reported ranging from .25 cents to 4.5 cents, the average being 2.42 cents.

In creameries receiving not more than 3,500,000 pounds of milk, cost reported ranges from 1 cent to 4 cents, average being 2.2 cents.

In creameries receiving more than 3,500,000 pounds of milk, cost ranges from 1 cent to 4 cents per pound, the average being 1.79 cents.

The average price of fancy western creamery butter on the New York market for the past year has been 19.71 cents. During the preceding year the average was 18.85 cents.

During the year there were 137 creameries and cream stations added to the Iowa list and fifty-five closed. The total number is now 891. Of these 504 are operated by individuals, 349 on the co-operative plan, and 37 by stock companies.

The average monthly wage of butter makers in this state was $50.04 in 1897, and $53.63 in 1898. The average number of months employed was increased from 10.2 to 11. Average value of creamery plants is reported at $3,024. Last year it was $3,103. The decrease is believed to be due to a tendency to report actual rather than cost values. The average value of skim stations is given at $1,510; the total value of creameries and skim stations is $2,641,379. The average number of patrons to a creamery is 116; total number of patrons, 91,998. The average number of cows to the patron is seven; average to a creamery, 798; total number, 632,814.

New York is the greatest market for Iowa butter. Seventy-one per cent of the shipments to points outside the state go there. To Chicago goes 9 5 per cent, to Boston 8.1 per cent, to Philadelphia 3 4 per cent and to New Orleans 1.6 per cent. Still smaller quantities go to other points and three foreign countries are included in the list of markets. The dairy commissioner finds little encouragment for the cheese industry. Within the past year, eight cheese factories have been changed to creameries, seven have been closed and six new factories have been opened. The total value of the cheese produced annually in the state is approximately $350,000.

NOT ALONE IN KANSAS.

Modern thought and investigation are turning a search light on the loose, shiftless and unbusinesslike methods of conducting a dairy, which have been prevailing so largely for years all over the Union. The first real practical effort of this kind was the "Cow Census" of the township of Ellisburg, Jefferson Co, N. Y., taken by HOARD'S DAIRYMAN, through its correspondent, C. W. Jennings, in 1888. By this census it was disclosed that the cows of that township were actually bringing their owners in debt every year over $25,000.

Every farmer in the town of Ellisburg received a sample copy of the DAIRYMAN, which contained the figures of this census, and it woke them up "from a sweet dream of peace" to a realizing sense of the need of more intelligence and wiser methods, if they hoped to make any profit in keeping cows. The next effort was a "Cow Census" of the town of Bovina, Delaware Co., N. Y., taken by Mr. Geo. H. Powell and Mr. Jennings, under the direction of the New York Dairymen's Association. A much better state of things was disclosed here, but the same old lesson was uncovered, viz: that there were lots of farmers in Bovina keeping cows at constant loss, all because they did not value sufficiently the necessity of keeping up the grade of their dairy intelligence.

The third effort towards a "Cow Census" has lately been taken by Prof. Otis, of the Kansas Agricultural College, which disclosed the fact that in the narrow radius of one creamery, there were eighty-two herds which averaged only $19.79 worth of butter fat for the year, while a herd of the *same sort of cows*, owned by the Experiment Station, produced $37.75 for each cow.

What made the difference? Simply the use of dairy intelligence; that's all. The owners of the 82 herds did not think it worth while to read up and post up on the matters that belong to intelligent dairy farming. Very likely they did not believe in a balanced ration. Prof. Otis did believe in it. His study and reading, as well as experience, had taught him the value of it.

And so it goes. Wherever the search light of investigation is turned, whether it be by the individual farmer upon his own ideas or methods, or whether a whole community is included, everywhere it is seen that the way to the best profit with cows lies through intelligent study of dairy facts, dairy experience, dairy principles.

POSSIBLE BUT NOT PROBABLE.

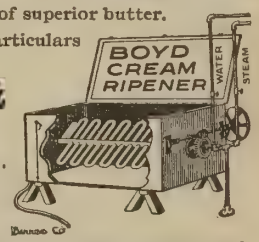
The recently issued *Bulletin* of the Storrs College Experiment Station contains matter on the question of tuberculosis, that makes very interesting reading just now. The bulletin summarizes the result of observations made by Prof. W. H. Conn, Ph. D., during a visit in Europe, where he had unusually favorable opportunities for visiting hygienic and agricultural laboratories and schools, experiment stations and dairying establishments.

"During the last three years the agitation in regard to the problem of bovine tuberculosis in Connecticut has been to a certain extent allayed," says Prof. Conn. He goes on to add that this is fortunate in so far as it has partly relieved the apprehension of the public in regard to the danger of the transmission of tuberculosis to man by means of meat and milk.

On the danger of the transmission of the disease from animals to man the bulletin has the following:

POSSIBLE BUT NOT PROBABLE.

Upon this phase of the subject there has been the greatest amount of interest and the largest amount of experimenting. It is the problem which is most vitally connected with human health, and which, more than all others, we desire to have positively answered. There has been abundant evidence collected to show that it is possible for the disease to be transmitted from animals to man, either by means of highly tuberculous flesh or by means of the milk of animals suffering with tuberculosis of the udder. Experimental evidence in this direction, which has been accumulating for ten years, apparently puts the conclusions beyond dispute. But the more this subject is studied the more it becomes manifest that the danger of such distribution is comparatively small. There are indeed those who think it may be neglected entirely in view of the other more common sources of the disease in man.



While tuberculosis among cattle has been rapidly increasing in recent years tuberculosis in man has been declining. Bovine tuberculosis has apparently increased many fold in the last fifty years, while human tuberculosis has diminished nearly 50 per cent. While such statistics of course do not show that tuberculosis is not transmittible from animals to man, they do indicate clearly enough that the tuberculous flesh and milk cannot be regarded as very important sources of the disease in mankind. Man is evidently open to other sources of infection so much more important than that of the milk or flesh of cattle that it is doubtful whether his danger of taking the disease would be rendered appreciably less if we should exclude milk and flesh entirely from our diet. These statements apply more strictly to adults than to children. For although there has been this large decrease of human tuberculosis in general, it is found that the amount of intestinal tuberculosis in children has not decreased as much as the other forms of the disease. This is thought to indicate that the danger of children contracting tuberculosis through the use of raw milk is a considerable one. There is, however, practical unanimity of opinion that an adult has little to fear from this source.

Admitting all that Prof. Conn says to be true, the wise dairy farmer will not lessen a whit, every effort by the tuberculin test and sanitary care, to cleanse and keep clean his herd from tuberculous taint. He will do this for his own sake and to preserve his property in the best possible efficiency for his own profit. He will constantly realize that the disease is communicated by infection, from one infected animal to another, the same as small pox in humans, and it is his business to keep the disease out of his herd.

Home Cheese Making.

We can not tell all about making cheese in a brief article, but we will give the outlines of the process and skill will come with experience. Little, if anything, need be purchased specially for home cheese making on a small scale. A good, well cleaned wash boiler will answer for a vat; an old peck measure with the bottom knocked out of it, will answer for a hoop; any farmer's boy can make a "follower" for such a hoop by cutting it from a piece of board. It should be round and of a size just large enough to fit inside of the hoop, and should be battened across the grain to prevent it splitting. A clean basket, some cheese cloth, a thermometer, and some rennet, will be all that is necessary besides. With 3.5 per cent milk, calculate to have about ten pounds of milk, or, say, five quarts, for each pound of cheese to be made. If a sufficient quantity can not be had from one milking, keep the night's milk very cool and add it to the morning's milk, so that the former may undergo as little change as possible. Put the milk in the wash boiler and heat to 85 degrees F. by the thermometer, then add rennet enough so that coagulation will begin in about fifteen minutes and be completed in about forty minutes. It will be better to buy from a dairy supply house, rennet extract or rennet tablets, for these have known strength and are accompanied by directions telling about the quantity to use for a given amount of milk, whereas if one attempts to prepare his own rennet there will be a good deal of guess work about it. The quantity of rennet to be used depends somewhat on the season, the condition of the milk, the length of time the cheese is to be kept, etc , all of

TESTED BY THE MILK PAIL
Quaker Dairy Feed
Quaker Dairy Feed is made entirely of grain — principally of oats—combined in scientific proportions. It is complete for the production of milk and the proper maintenance of the animal.
Sold only in sealed and branded sacks.
OUR FEED EXPERT.
We wish to come as close to the consumer as possible, and freely offer the personal services of our Feed Expert in assisting in the solution of feeding problems. Parted In A Dream—(New) Pronounced by critics a beautiful song. Very popular. Founded on strange incident of Cuban war. Regular price, 50c. Sent to our readers for 25 cts., post-paid, including also miniature page of DARLING LENORE and MOTHER'S DARLING YET.
Darling Lenore—(New) Is called a very catchy, pretty song with beautiful flowing melody, all in waltz time. Becoming very popular. Regular price 50 cts. Sent post-paid to our readers for 25 cts. with a miniature page of PARTED IN A DREAM and MOTHER'S DARLING YET.
Mother's Darling Yet—(New) Pronounced very pretty. Is extremely popular with singers of lullaby songs. Regular price 50 cts. Sent post-paid for 25 cts., and with it a miniature page of PARTED IN A DREAM and DARLING LENORE.
For 2 cts. I will send one miniature page of each of the three songs. Address the author,
HALBERT L. HOARD, Fort Atkinson, Wis.

which are matters of detail that the operator must learn by experience. After it is added the curd should be ready to cut in about forty minutes, if the amount of rennet and degree of heat have been right. To tell whether it is ready, pass the finger under the surface of the curd about half an inch. If the curd breaks clean before the finger, leaving only moisture behind, it is ready. The whey should have a greenish cast and be nearly transparent. If it seems milky there has not been enough rennet or not enough heat. Don't try to cure this mistake this time, but remember the experience for the next attempt.

Cut the curd into small squares to allow the whey to escape, then drain off as much of the whey as possible, scald and rinse a sufficiently large square of cheese cloth, spread it in the basket that has been provided, hang it over a vessel of sufficient size to catch the remaining whey that drips out, and place the curd on the cheese cloth to drain. When drained, break up the curd with the fingers, until it is fine and salt it to taste. Approximately the amount of salt required is about a teacupful to ten or twelve pounds of cheese. Mix the salt very thoroughly, gather up the cloth by the four corners and shake well, lift it out and put it in the hoop which should previously be placed where it is to be pressed.

And here a word as to the pressing. A very good home-made press may be made by hinging or hooking a pole or scantling ten or twelve feet long to the wall, two or three feet from the floor. The hoop containing the curd is set on a clean board on the floor near the wall, the cheese cloth is spread over it as smoothly as possible, the "follower" is placed on the top and an upright piece of wood is set in, the lower end resting on the "follower," and the upper underneath the lever above referred to. The amount of pressure can then be regulated by hanging weights on the outer end of the lever. The pressure should be quite moderate at first and gradually increased, and the curd should remain in the press for twenty-four hours and should be turned once during that time on a clean, wet cloth. Then take the cheese from the press, set it away to dry for a short time, after which rub it thoroughly with melted butter. Turn and rub it in the same way every day for a week, bandage it with cheese cloth and cure it in a room that is cool, dry and well ventilated. Cheese will cure in from thirty to sixty days, depending on its size and the conditions under which it is kept, but it will continue to improve for a considerably longer time. These directions will enable our correspondent to make a start, and should obstacles be met with, we will try to advise with regard to them if within our power. It is customary to make cheese during the summer season. If made at other seasons, the milk in the vat must be heated two or three degrees warmer, and more attention will have to be paid to keeping the temperature up to the right point while coagulation is going on.—*Homestead.*

A Successful Texas Cheese Maker.

Mr. G. C. Freeman, who resides seven miles south of Denison, Texas, has solved the problem of succcssful cheese making in that state. In a recent interview with the Dallas (Texas) *News*, Mr. Freeman, who was a former New York cheese maker, makes the following statement:

I came to Grayson county in 1876 from my native state, New York, where I was engaged all my life in the dairy business, including the care of milk, and the making of butter and cheese. All that time I have lived near Denison, with the exception of four years that I spent in New York state after I came here first. When I first came to Texas, I was of the opinion that good butter and cheese could not be made here for two reasons, the first was that the food and water were not of the right quality, and the second reason was the climate. Since then for many years I have been engaged in the work, however, and I have changed my mind.

Ten years ago it was almost impossible to get a pound of Texas made butter that was fit to eat, and today there is an enormous quantity of Texas made butter that is as good as any made anywhere in the world. This change has been brought about by the development of Texas, the improvement of the cattle, the improvement of the methods of caring for cattle, for watering them, and finally for caring for the dairy and dairy product. These things have worked wonders, and let me remark right here that in ten years from now North Texas will be covered with dairy farms. The cotton will gradually disappear, will drop out, because your land here is too valuable to put in cotton, and no land in America is better adapted to or suited to dairy farming and manufacture.

When I first came here I was prejudiced against the water. Now, after investigation and practical tests, I know that there is as pure water here as anywhere. The matter of food for dairy cattle is no harder of solution here than anywhere else in America, because the soil here produces all the food stuffs as bountifully and as good quality as any country. The climate is as favorable to the manufacture of dairy products as any climate I have ever worked in. You understand that I believe food and water to be the essentials for successful dairying, and there is no greater abundance of either than right here in North Texas. I say this as a matter of knowledge and as a fact, for experience has proven it to me. I am selling cheese of my own manufacture in Denison that I will compare with any cheese from any country. What I say I can demonstrate to the satisfaction of any doubter, and I repeat that in a few years North Texas will turn from cotton to dairying as the principle industry. In a few years Texas will be supplying other sections with their dairy product, instead of spending thousands of dollars every year for dairy products from other states. This is not a matter of prophecy, but a matter of business. I believe this will happen, because the people are turning their attention to that which is most profitable and to which their country is best adapted. They are learning that to make money they must keep their money at home; that to prosper they must supply that for which there is the greatest demand and in which there is the greatest profit. In cotton, Texas must compete with the world; in fruit raising, dairy products and the like, she has only to compete with her home people, keep the money of Texas at home—for in these things when Texas once gets started at them there will not be a possibility that any other section can compete with her.

Feeding Wheat to Calves.

ED. HOARD'S DAIRYMAN:—I have seen from time to time in your paper how to feed calves. I have raised some this winter, and never have had any that did as well. I have fed nothing but ground wheat; have been surprised that I have not seen it recommended in your paper. I wet it with cold water, then scald it thoroughly; stir it up till it is smooth; add what milk you want to, but my calves got very little milk after they were a few weeks old. E J. L.

Binghamton, N. Y.

WASHING DISHES

A mountain of dishes confronts the average housewife after all the family have dined. They are greasy dishes, too, and hard to get clean with soap and water. The best, easiest, quickest and cheapest way to wash dishes is to use a little

GOLD DUST

WASHING POWDER

in the dish-water. It acts like magic, cuts the grease and makes the dishes perfectly clean. In fact all cleaning is made easier by this great cleanser, and at half the cost of soap.

For greatest economy buy our large package.

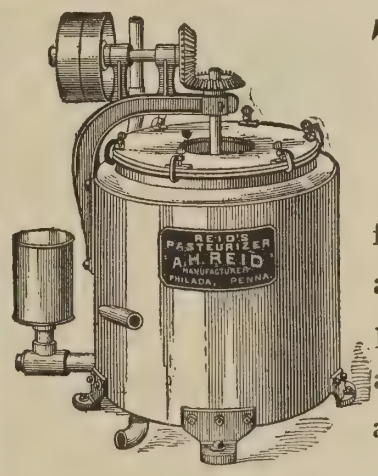
ASK YOURSELF A FEW QUESTIONS



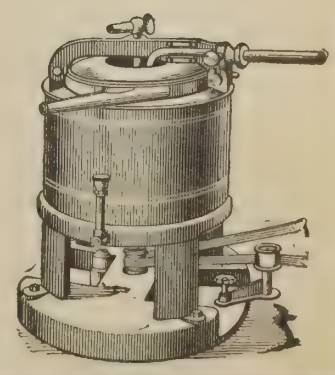
If Deering Ideal Harvesting Machines are not the best in the world, why is it that the Deering works are the largest in the world?

If there is not a greater demand for Deering machines than for any other make why is it that the Deering works employ over six thousand five hundred skilled mechanics—more than twice as many as any other reaper plant in the world?

If Deering machines have not earned the right to universal approval why is it that the Deering works are increasing the output for 1899 by 50,000 machines as against the product of 1898?

If Deering ball and roller bearings are not applied to binders and mowers in the only correct way why is it that competitors are at their wits' ends to make their machines as light draft as the Deering Ideals?

DEERING HARVESTER CO., - Chicago.



They All Admit It.

Even the strongest opponents of pasteurization are forced to admit these facts; it kills all germs, and removes all garlic and odors or taints in the milk; pasteurized cream produces a more uniform quality of butter, under varying atmospheric conditions and makes the butter keep longer and retain its flavor better.

Whether you sell your cream or make it into butter, get a

REID Pasteurizer.

The Grain Crop.—Dairy Conditions.- Spraying Wild Mustard.—Five States Milk Producers' Association and the New York Milk Trade.

ED. HOARD'S DAIRYMAN:—Ten days since, the farmers were praying for rain; hay had advanced within a month $3 per ton, and on some farms preparations for an increased acreage of sowed corn were being made, in anticipation of a short hay crop, because of the four weeks drouth which was holding the boards; but, suddenly a change came o'er the spirit of these farmers' dreams, the cause of which were copious showers, which have continued at short intervals, accompanied with cool weather during the last ten days.

One result was a killing frost on the morning of Monday, the 15th, which knocked out the small fruit at a great rate. But the rains, although cold, have greatly benefited grass and spring sown grain, while winter wheat never promised better than at this season of the year.

Cheese sold on the Watertown Board of Trade, last Saturday, at 9⅛ cents, fully 2 cents higher than at last year the same date; a condition which makes the dairymen "smole large smiles."

Butter, however, is off nearly 2 cents per pound, from this date last year, a change which shut off the separators and opened the cheese vats at our factory, a week or two earlier than usual. The factory is turning out thirty-one cheese of sixty-five pounds each, per day, and will now change to eighty-five pounds cheese.

There is quite an increase of milk over former years' delivery, at this time, owing to the shutting down of two or three small factories in the eastern and central parts of the town, due to the opening of the creamery at Adams last fall, a number of the patrons having deserted that concern, and are drawing their milk here. Another vat will have to be added when the June flush comes on.

The Belleville factory now turns out more cheese than does any other Cheddar factory in Northern New York, while the quality produced is second to none.

With the present efficient management and staff of skillful cheese makers, and the Babcock as umpire and referee, everything is lovely, the outlook promising, and no one is kicking. Of course, as a rule, but few, if any, of the sixty-five patrons ever saw or heard of Jenkins' Organ, else some of the 3.3% cows might look over the fence at some of their neighboring 4.6% producers, and say, "Go to; if it were not because of dishonesty, ignorance and favoritism, our milk would test as high as yours, while we are giving twice the amount you give."

In a recent issue of the *Country Gentleman*, one of its English correspondents says that spraying "charlock" or what is known as wild mustard, with a solution of two and one-half per cent of sulphate of iron will eradicate it.

That weed has become a great burden on some farmers in this town; it and the white daisy having taken almost full possession of some fields. If this solution will destroy the charlock, provided the farmers can be persuaded to apply it, at least one of these pests may be driven out. Sulphate of iron is not costly nor difficult to be held in solution, while it may be applied to the meadows or pasture, through the use of any of our power sprayers. The difficulty, however, of coaxing the farmers to apply it, will be found the greatest obstacle to its adoption.

Mr. Ira L. Snell, of Kenwood, N. Y., has been interviewed by a Unica *Herald* man, and has told him that the so-called "Five States Milk Producers' Association," is, Phoenix-like, about to rise from its nest of ashes and make a noise, at least among the milk dealers of New York city, and that very soon. He also told the reporter that, notwithstanding there was an increased daily average of 1,301 cans of milk during the week ending May 8th, over the same week last year, there was an increase of 15 cents per hundred pounds, over the price of the same week last year. This, he says, is due to the efforts of the association to equalize the profits between the retailers and producers. At the present price paid per hundred, farmers get less than 2 cents a quart for their milk, and in New York, milk is sold at prices ranging between 6 and 15 cents. The farmers only demand 2½ cents per quart, which is only reasonable when the retail price is considered."

The foregoing would be all right, but for two or three objections. First, just how an association, which is no association at all, since it never has been perfected, nor handled a quart of milk, has been able to force the price of milk 15 cents per hundred pounds above last year's figures of this date, is not made quite clear. Second, milk does not sell from 6 to 15 cents per quart. Much of it, Mr. George A. Smith, who a year ago, spent several weeks among the milk and grocery stores in the city, says is sold for 4 cents a quart, the dealers making it a pointer to call other trade; while 15 cents is seldom reached, except for a few dairies such as ex-Governor Morton's Guernsey and Mr. Havemeer's Jersey herds. The 6 cent milk is peddled in the wealthy resident portion of the city, and cuts but a small figure in the milk trade. Mr. Smith had ample opportunities for learning the true situation of affairs, engaged as he was in looking after adulterated milk and oleo, as one of the experts of the Department of Agriculture. Third, the advance in the price of milk is not due to the influence of the "Five States," or any other organization, but to the advance in the price of cheese, instead, which is at least two cents higher than last year at this season.

Every one at all familiar with the New York milk trade, knows that the retail price there is always based on the price of cheese, or, rather, its value for cheese. When cheese is high, the price of milk goes up in the city; when it is low, down goes the price of milk to the producer. If cheese were to suddenly drop to the level of last year, does any body believe that the 15 cents per hundred advance would be maintained a day? Hardly, unless one knew nothing of the situation, or else pretended to believe it, for the purpose of fooling the milk producer. Every true friend of the dairymen would heartily rejoice at the result, could the price of milk, to him, be raised to 2½ or even 3 cents per quart on the platform; as, at those prices, even a good fair profit at the present average retail price in the city, would be reaped by the dealers there, because of the enormous amount handled by them. But, if this increase is not to come until after the Five State Association has turned the world upside down, by getting control of the larger part of the milk trade in Greater New York, I fear the date will be found a long way in the future. There are more than 4,000 stores in the great city, where milk is retailed, and there is too much money behind the present milk exchange to allow of any such happy—to the dairymen—results.

Mr. Snell also told the reporter that the various railroads, which discharge their freight each day, in New York, receive annually, at least, $3,000,000 in payment, and it goes without saying, that this branch of freight business is the most profitable to the roads, of any carried. Another point; should this *in embryo* association materialize, and thus bring forth such wonderful results, it is safe to say that the prices paid by the association would not only close every cheese factory and creamery, located within four miles of these railroads,—and extending across each of these five states, but that the railroads would extend their lines of stations further still. Already milk goes from New Haven, a port on the south shore of Lake Ontario, in Cayuga county, to Philadelphia, Pennsylvania, and there is nothing to prevent the New York Central from starting milk trains from along its St. Lawrence River Valley branches, within three weeks, should the conditions of the New York City milk trade warrant such a move, and as there are nearly 100,000 cows in St. Lawrence county, nearly one-half the milk product of which could be shipped, and fully 30,000 more in Jefferson county which could be added, to say nothing of the extension that could be made along other lines and in other localities, it looks to one, somewhat familiar with the situation, like a "dream in Utopia," to make any such promises as are recorded of this association.

Seasonable Notes from Michigan.

Factory Skim Milk for Calf Feeding.—Farm Butter.—Galvanized Iron in the Dairy.

ED. HOARD'S DAIRYMAN:—Pastures are good and cows on grass giving fine messes of milk. Patrons of some creameries are having trouble with the returned milk. It is brought back supposedly sweet, yet calves refuse to drink it. In fact, some of it is not in very good condition, and no one could blame them for turning up their noses at it.

One of our neighbors commenced sending his milk to the creamery this spring, but discontinued his patronage after a short time. In spite of care in cleansing cans and cooling the milk, his calves refused to touch it after it had come back to the farm. Add to this the fact that all milk received is pooled, no test being made individually, and it became evident that he with his Jersey cows was playing a losing game.

Now the churning is done at home, even though a man must leave the farm work to do it. Private customers were engaged in the county seat and peace restored in the calf pasture.

Any creamery which refuses to buy or handle milk by test is unfavorable for those patrons who have rich milk. Such milk goes to keep up the average and those with poor cows, that is, cows which test low, are profiting at their expense.

The only fair way is to test each patron's milk separately. Indeed, this plan is now practiced generally, only an occasional instance being found where no such test is made. It is not to be wondered at that owners of three per cent cows, giving only an ordinary mess, should say in this case that they find the creamery just as satisfactory, or even more so, than home manufacture. It is the other fellow who does the kicking—and with good reason.

While in the principal grocery store of an adjoining town, the other day, in conversation with the proprietor, the conversation fell upon butter. Upon making inquiry as to the quality of that brought in by farmers,

Pure Bred **Tamworth Pigs,** Bacon curers choice. Pure Bred **Ayrshire Cattle,** largest imported herd in America. Stock all ages for sale. E. G. STRACY, Box 720 Brockville, Ont., Canada.

St. Lambert Jerseys, all ages, both sexes. Some from tested cows at low prices. W. J. HUSSEY, Mt. Pleasant, Ohio.

Write for what you want. Visitors always welcome.
JOHN E. ROBBINS,
Greensburg, Ind.

the following is in substance what was gleaned:

The quality is very un atisfactory, the great bulk of receipts being unsatisfactory to dealer as well as consumer. If a crock of good flavored butter comes in, nine times out of ten, it is so salted as to spoil it. It seems to be the aim of the maker to get in just as much salt as possible, so as to make it weigh heavier.

Sometimes a crock of butter comes in which looks very nice on the surface, yet an inch below, it is found ring-streaked and speckled, having every appearance of being dumped in right from the churn with no working whatever. The surface veneering is expected to sell it at market price without any other inspection.

Much of the butter bought is known to be inferior, yet is taken in, because there is nothing better offered, and then it often happens that it is the best customers who make it and it would never do to give offense, which would certainly be the case were the butter refused.

What can be done to improve the quality of farm butter?

Pay for every pound of it on its merits. No farmer expects to receive the same price for grain that is shrunken and poor that his neighbor does for that of superior quality. There is distinct grading and every one offering grain for sale expects to be paid accordingly. Take it with wool, wood, or produce of any kind sold off the farm, with the exception of butter, all sell on a scale graded as to actual value. Why should this discrimination be made in its favor?

The writer is firmly impressed that one of the best methods of improving the quality of farm butter after it has been made the practice by all dealers to buy and sell it only on its merit, is to make the county fair a school of dairy instruction. This has been tried in our state, and as one who has had opportunity to see the result of its operation, I can heartily endorse it.

Everybody goes to the fair and a class of of farmers and their wives are there reached who never attend a dairy convention or even an institute, and it is this class largely who most need the instruction which might there be obtained.

It only needs one day at a fair where practical instruction in butter making is in operation, to convince the most sceptical of the good resulting therefrom. To see the crowd surrounding the operator, to hear the questions coming in thick and fast, to note the eagerness with which the score cards are examined, and the expression of interest in the explanation as to why this butter is better than that, all this is encouraging and indicates that good seed dropped in this way will take root and bear fruit.

It is my desire to have a suitable dairy instructor in attendance at every fair throughout the land. Where this has been done it has proved a drawing card in securing attendance, farmers coming long distances for the express purpose of hearing the dairy lecture, and bringing samples of milk to be tested.

It is none too early now to begin to agitate this subject. Let dairymen present the matter to the directors of their agricultural societies and see if provision for something of this kind cannot be made in time for the fall fairs. Competent instructors ought to be obtainable through the different agricultural colleges and dairy schools at reasonable rates.

In regard to the inquiry as to the use of galvanized pails, I can state this from personal experience. They are very hard to keep clean, one short trial convincing us that we preferred tin. The surface is not smooth as with tin, and soon gets a sort of deposit in spite of all ordinary precaution. Even with a galvanized water pail or hand basin this will be observed; it soon becomes dingy and scouring or scrubbing has little effect upon it. Good, heavy tin is the best material we have found for dairy utensils.

Mich. W. C. ROCKWOOD.

A Successful Gathered Cream Creamery.

ED. HOARD'S DAIRYMAN:—We have quite a number of farmers that have the hand separator on the farm. The rest raise their cream by the gravity system. The secret of our success is in

1st. Having our patrons keep their cream in good condition. We gather it every other day.

2nd. The large amount gathered makes the cost to gather very small, less than ¼ of a cent per pound.

We have not sold a pound of butter for the last three years that has not brought us the price of western extras.

I will enclose you our annual report, from which you can get an idea how we keep our business. These we have published, so as to give one to each patron every year, that they may know what the business cost to run it.

REPORT OF THE OSAGE CO-OPERATIVE CREAMERY COMPANY FROM JANUARY 12, 1898 TO JANUARY 11, 1899.

Cash on hand at last report	$ 378.90
Cash received from sales of butter	61,366.52

Number of pounds sold in home market	23,537

A. BARTLE, Manager and Secretary.

The Guenon Theory.

ED. HOARD'S DAIRYMAN:—Have just been reading the article by J. J, page 237, and being desirous of gaining information to properly judge a dairy cow, I write to ask what the "Guenon" theory is; its explanation may be of interest to other subscribers.

I am a close student of the cuts in the issues of the DAIRYMAN, and hope to be able to make good selections, when increasing my present herd. I find the information in each issue of great interest and value and of greater benefit than any other paper I receive.

My herd consists of 7 head grade Jerseys, with first calves. One cow has just dropped second calf. From the six I have been milking (all fresh since Jan'y except one) I am making an average of 25 lbs. butter a week, which seems to be a rather small output, considering the feed I have been giving.

Cows have had, since the middle of February, pasturage for one and a half to two hours each day upon rye, and are now upon oats (freeze having killed out to unprofitable stand to cut) with additional picking in regular pastures, also mixed hay and shucks in barn, while grain feed has been from six to eight pounds daily, of mixture of 16 lbs. corn meal, 8 lbs. bran, 8 lbs. cotton seed meal. Any suggestion tending toward an increase of yield will be greatly appreciated.

Am preparing for a separator which will be in place this month. Shall increase my stable soon to hold 20 head, and shall put in a silo, about 8 or 10×20 feet, and fill with mixture of corn and cow peas, load for load.

Market for butter is good at 25 cents the year around, and I am anxious to put myself as near the top for quality as possible, and HOARD'S DAIRYMAN is boosting me a little week by week.

Am raising three Jersey bull calves—two three-fourth grades, one full blood, all from Pogis stock, from which I shall make a selection to head my herd.

I have written considerable but shall "ask" for more in the future.

FLORIDA CRACKER.

As it requires a book to fully explain the Guenon theory of judging cows, it cannot be expected of us to go into the details of that theory and their application. The system is founded upon the assumption that the escutcheon, which is sometimes called the milk mirror, and consists of the fine upgrowing hair on the rear part of the udder, on the thighs and between them, is an index of the dairy capacity of the animal. There are various classes and sub classes and other divisions, to each of which is assigned comparative and specific values, but in a general way it may be said that the larger and more regular in outline the escutcheon is—especially if branching well out on the thighs—the greater the value ascribed to it as indicative of a pronounced dairy ability.

So far as our observation extends, less reliance is placed upon this "sign" than formerly and more attention is given to the general contour and outline of the animal. We cannot say that there is no relation between this up-growing hair and natural capacity for milk giving, because it is entirely possible that nature, in anticipation of the demand upon the parts for a large udder and room for it, gives a peculiar texture and flexibility to the skin that causes the peculiarity to which the name escutcheon is applied; but personal observation has not sufficed to warrant us in placing over much faith in Guenon's theories. Nevertheless we like to see a nice escutcheon, but would not reject an animal otherwise satisfactory for the reason that the escutcheon might be pronounced unsatisfactory by others.

In the matter of selecting one of those bull calves for future service, while we advise giving a good many points to the full blood, we would not entirely overlook the merits of the dams or the form of the calves themselves.

In the matter of the grain part of the ration as reported above we incline to the opinion that the mixture is too concentrated for best results. Both corn meal and cottonseed meals are what are known as heavy feeds, and unless considerably diluted or extended with some much lighter material, are very difficult of digestion. We should certainly prefer to transpose the amounts of bran and corn meal or at least to reduce the amount of corn meal by fully 50 per cent.

To Cure a Self-Sucking Cow.

ED. HOARD'S DAIRYMAN:—To prevent a cow from sucking herself, or another, take a piece of wire, about No. 9 or less, and put in the same as a ring, bring together, hold with pincers and give half turn, then bend the two ends, like the prongs of a fork and about two inches long.

S. B. MCCLUNG & SON.

Ottumwa, Iowa.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Two yearling bulls from dams giving 60 lbs. and 71 lbs. each. Test 4.5 and 3.6 each. W. R. GATES, Ripley, Jefferson Co., Wis.

Outlook of the Cheese Industry in Wisconsin.

[Paper read before the Wisconsin Cheese Makers' Association, at Madison, Wis., by W. W. CHADWICK.]

According to the last report of the Department of Agriculture there are 15,990,115 milch cows, nearly 16,000,000, in the United States. In 1895 an enumeration of the milch cows in this State, two years old and over, was made for the first time, and the number reported was 842,039. Of this number the milk of about 200,000 is used to manufacture cheese.

It has been said that "Americans *taste* cheese, while Europeans *eat* it." In Great Britain and most of the countries of Europe, cheese is one of the chief articles of food. They use it as freely as we do meat. This substitution is found to be economical and satisfactory to consumers. In these foreign countries the consumption of cheese, per capita, is several times as large as in the United States. It seems clear that a taste for cheese has never been generally acquired in this country. One reason is that we have cheaper meats, and the consumer does not have to pay as close attention to the cost of his table.

According to our last Dairy and Food report, we have 1,571 cheese factories in our state, and we manufacture about one-fourth of all the cheese in the United States. I have visited many of these factories, to ascertain their condition as to location, cleanliness, condition of milk, and if filled cheese was being manufactured. We received many communications soon after the laws suppressing the manufacture of filled cheese, and regulating the manufacture of skimmed cheese were enacted, in 1895, asking us to visit various cheese factories and creameries where the informants thought the laws were being violated, but we were unable to find any filled cheese being manufactured. I found some skimmed cheese being made in Manitowoc county, contrary to law. I made complaint against the party and he pleaded guilty, paid his fine, and said he would sin no more.

The cheese industry is not all it should be in our grand, good state, where we have the right soil, grasses, water and climate for its production. I have visited several hundred cheese factories and creameries in this state, during the past four years. I have taken the average test of 27 of these, in as many different counties, during different months of the year, and find the average amount of butter fat in the milk delivered to be 3.7 per cent.

Many of our farmers pay no attention to breed or breeding of their dairy herds. We all know that when proper care is given to the right kind of sires, that the result is better milk. We cannot expect good cheese to be made from poor milk any more than we can look for good bread from poor flour. In order to produce good milk we must have good healthy cows, provided with the right kind and quantity of wholesome food, and keep them in perfect health, giving them the proper amount of exercise, pure water, fresh air, and in stables properly ventilated.

Too great care cannot be given milk. Much of the milk delivered at the various factories I have visited in the state, is too filthy to be used for making cheese. It is drawn from cows in a dirty stable, put in a dirty can, then in a dirty wagon, and delivered at the factory by a dirty person. Many of the cheese factories are located near sloughs, pig-stys, barnyards, and other filthy places, and are not kept clean. Most of the trouble in the various factories is caused by filthiness.

In many parts of the state there are too many factories of inferior quality, because farmers want to have their milk delivered but a very short distance. It would be much better to have better factories, and a less number of them, as cheese can be manufactured cheaper where 6,000 pounds is delivered daily, than where only 2,000 is delivered.

I have visited a number of factories and found many of them have made poor cheese, and they were at a loss to know the reason why. In most of the factories where Swiss cheese is made, they have as many barrels for whey as there are patrons. These barrels are usually sunk about a foot and a half in the ground, and the whey is dipped from the barrels with a pail. Some of that whey is put in the barrel in the spring and remains there all summer, for the barrel is not washed from spring until fall. I think a galvanized steel tank should be in use for the whey at every factory, and it should be thoroughly scalded and cleaned every time it is used, just as carefully as the cans in which the milk is delivered.

Too much cannot be said in favor of our Dairy School, for I have noticed that all over the state, where graduates from there have been employed, that good goods have been made. It was my good fortune to be Supt. of the Dairy Department at the State Fair one year, and I noticed that a large number of prizes were captured by our dairy students.

It has always seemed to me, and my observation has borne me out in thinking, that milk should be sold by the test instead of by the hundred pounds. There is no more reason why milk should be sold by the hundred, regardless of the per cent of butter fat it contains, than that oats should be sold by the bushel regardless of weight. Where milk is sold by the hundred, and a large part of it that is made into cheese is sold in that way, I often find that one and sometimes more of the patrons adulterate their milk by either skimming or watering, and sometimes they do both. When complaint is made against them, they either plead guilty and pay their fine, or they are tried and usually convicted. After having visited a factory and convicted one or more dishonest patrons, the milk delivered is always very much better, and I have received many letters stating that it takes one and sometimes two pounds less milk to make a pound of cheese. I have visited some of these factories a second time, and have always found them in better condition.

Every dairyman should test each cow in his herd with a Babcock tester, and if any cow is not paying for her keep she should be disposed of as soon as possible and a good animal secured in her stead. When we have a person in our employ who does not earn half his wages, we very soon find someone to take his place. If all our dairymen would secure the right kind of sires, the milk of the whole state would very soon average 4 per cent of butter fat, that being a gain of 3-10 of one per cent over the present average. This would alone add at least 4,000,000 pounds per annum to our present yield.

As to the future of dairying in our state, I think there is no limit to its possibilities. The reputation of our cheese product has been very much damaged by the filled cheese that was made a few years ago, but now that its manufacture has been entirely prohibited, there is no reason why we should not be a much closer second to New York state than we are at the present time.

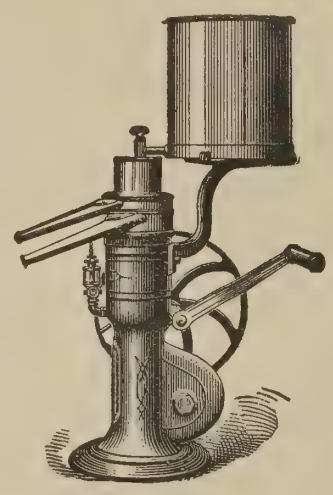
I am a firm believer in expansion of the cheese business, as I think there is no doubt that we can double and perhaps treble our production when we have all the land in northern Wisconsin in cultivation, that is now waiting for the industrious and honest dairyman.

New York Farm and Dairy Notes.

Among the Dairymen.

ED. HOARD'S DAIRYMAN:—During a trip through the finest dairy country in Delaware county, I was able to make some observations which may interest your readers. One who follows the west branch of the Delaware river through Delaware county, will see some of the best improved dairy farms in the state. Many of our most progressive dairymen live on these farms, and anyone interested in dairy matters, would profit by an interview with these men.

I think nowhere else in this country are there so many thoroughbred cattle, as in Delaware and adjoining counties. The Jerseys and Guernseys bred in this county have become so noted, that dairymen in other states buy their stock in this county for breeding purposes. On one small farm I visited, sometime ago, the owner was keeping a very fine herd of Jerseys. He was keeping one cow on every two acres. Only a small part of his farm was used for pasture, and the remainder was used for growing crops to feed the cows. His plan of farming was that of partial soiling. His earliest



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

crop, which he used for soiling his cows, was wheat. He preferred wheat to rye. The wheat was cut when the straw was green, and fed the cows. This was followed by oats and peas.

He had much to say in favor of oats and peas for an early soiling crop. They come in just the right time after the rye or wheat, and by sowing them at different times, they will last until the corn fodder is ready for use. He thought the fertility of the soil was best maintained with oats and peas, because the stubble left on the ground after cutting them was more valuable for plowing under, than that of most other crops. He did not have a silo, for he did not wish to do the work required to cultivate and handle the ensilage corn, as he was quite an old man.

For the reason that he carefully saved all the manure, he was able to grow very large crops of hay, some of his meadow would yield three tons per acre. The butter made from the Jerseys was sold to consumers in the village near by, but a part of the milk was fed to the calves sweet, without skimming, for he could make the most money, with the least labor, by growing calves from his pure bred cows, that he could sell for fancy prices.

METHODS IN POTATO CULTURE.

This is not a dairy topic, but most dairymen grow more or less potatoes, and some methods practiced in this locality, may have some good points for them. The modern implements for growing potatoes have so reduced the cost of production, that the farmers find some profit in growing them for the market. I know one man, who has a large dairy, who has made considerable money in growing potatoes. The most of the large growers now use the potato planter, the weeder, the best cultivators, and the potato digger. Those who cultivate the river flats, have land so easily tilled, that they are able to grow a crop of potatoes, and do the work nearly all by horse power.

I found one farmer who practiced a method that may be of use to some farmers who do not use the potato planter. The potatoes are planted on sod ground—a clover sod is preferred. The sod is turned with a reversible plow, and a wheel and coulter should be used, so each furrow can be turned evenly and smoothly.

After turning one furrow on one side of the field, commercial fertilizer containing a large per cent of potash, is scattered along the furrow, at the rate of about 1200 pounds per acre; the potatoes were dropped in the furrow about one foot apart, and close to one side of the furrows, so the line of potatoes will come just where the furrows lap, then potatoes will grow up through the places where the furrows lap, instead of through the sod. In this way the potatoes and fertilizer are dropped in every third furrow.

A few days after planting, the surface of the field is finely harrowed three or four inches deep. This does not disturb the potatoes, as they are plowed under about six inches deep. The potatoes soon grow up through the sods, and are frequently cultivated with the smoothing harrow and weeder, until they are several inches high. Afterwards a one horse cultivator is used. The potatoes are dug with a one horse potato digger, so the hand hoe is not used in growing the crop.

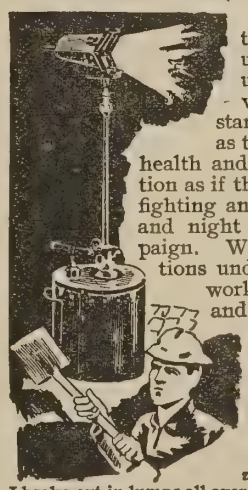
EARLY FROSTS AND DROUTH.

The most of the farmers here think the prospect is not very good at the present time for the hay crop. A drouth early in the spring, followed by several hard frosts, has not been favorable for the growth of the grass. In a climate where the conditions favorable for making the hay crop are so uncertain, there seems to be greater need of the silo. The ensilage corn can be made to grow well nearly every year, and it is one of our most certain crops.

The dairyman who has prospect of a short hay crop should plant more ensilage or fodder corn, and if he has no silo, he had better build one. If he must buy grain to supplement the hay crop, he will save enough by feeding ensilage to pay for his silo in one year. I speak from my own experience in building a silo. This is certainly good economy. Other dairymen have told me that the money saved from the grain bill, has paid for the silo the first year. W. J.

Delaware Co., N. Y.

Inaccurate Test Bottles.

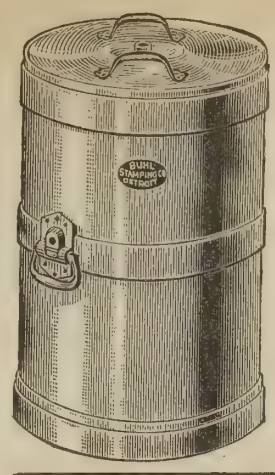


One of our dairy students, who is operating a creamery in Kansas, sent the writer two cream test bottles, during the past week, with the request that they be calibrated or tested. He writes: I have tested them, and find them to be wrong, but would like to have your test of them, so I can show the patrons that I am right." These test bottles were received, and an examination of them showed that the manufacturer must have graduated them with his eyes shut, or guessed at the places where each mark of the scale should be made on the neck of the bottle. The results of the tests of the scale on each bottle were as follows:

Correct Reading.	*Scale on Bottles. No. 1.*	*No. 2.*
1.	.2.	2.
2.	4.	3.5
3.	5.5	4.5
4.	7.0	6.
5.	8.5	7.5
7.	10.5	10.5
10.	15.	14.5
15.	22.5	21.5
20.	29.5	29
25.	36.	35.5

This is the worst case of inaccurate graduation of test bottles that has ever come to my notice. In the earlier days of the Babcock test it was not uncommon to find test bottles occasionally, that were not exactly correct, but at the present time nearly all the leading manufacturers guarantee their test bottles to be right. Even when this is the case, accidents may happen in the best regulated establishments, and anyone who owns and uses a Babcock test considerably, ought to be able to test the accuracy of his glassware. This is very easily done with a one centimeter pipette, which is graduated to fourths of a centimeter. Such a pipette can be obtained from dealers in chemical supplies. It may be used as follows: Fill the test bottle with water to the zero mark, remove with a strip of paper any water sticking to the inside walls of the neck of the bottle above the zero mark, then measure very carefully one c. c. of water from the standard pipette into the test bottle neck. If it has been graduated correctly, this one c. c. of water should just fill the scale from zero to the five per cent mark on the neck of the test bottle. A second filling of one c. c. water should fill the scale to the ten per cent mark. One centimeter in volume represents five per cent of fat in the Babcock test, and by taking this standard, the correctness of the graduation on a milk or cream test bottle can be ascertained. E. H. FARRINGTON.

Wis. Dairy School.



MIGHTY HARD WORK.

Some men have to do their work under all sorts of unusual and adverse circumstances that are just as trying upon their health and physical condition as if they were soldiers fighting and marching day and night in a hard campaign. When the conditions under which a man works are abnormal and unhealthy he needs to take special precautions to build himself up to withstand the extra strain.

"In 1894, *I was working at night* and I broke out in lumps all over and when these left the skin peeled off," says Mr. John A. Calloway, of 218 26th St., Columbus, Georgia, in a recent letter to Dr. R. V. Pierce, of Buffalo, N. Y. "I had catarrh for four years and also liver and kidney trouble; when it would commence troubling me I would have a slight aching a little below the chest. I used many kinds of medicine but received no benefit. My eyes were sunken and my face was pale; I had pimples on my face and there was brown spots on my face. Now these are all gone. I took six bottles of Dr. Pierce's Golden Medical Discovery and two of Dr. Pierce's Pellets. They are the best medicines I ever used in my life, and I do believe that I am entirely well. I have a good appetite but before I commenced treatment I had no appetite at all. Now I am like a child—ready to eat at any time of day or night. Last year I weighed one hundred and thirty-four pounds and now I weigh one hundred and forty-five. Please accept my thanks. I am so glad I found the right kind of medicine."

"Golden Medical Discovery" is free from alcohol; it is pure *medicine* and nothing else. Unlike the so-called "tonics" and "extracts" which tend to create an appetite for stimulants, the "Discovery" creates only a healthy natural *temperance* appetite for good food which nourishes and strengthens. The medicine dealer who says he has something "just as good" knows that he falsifies. If he urges an inferior substitute it is to gain a few pennies greater profit. No matter how discouraged you may be, write to Dr. Pierce for advice which he will send you free and which if followed, is bound to do you good.

The Best Factory Cans.

The strong points of the Buhl Factory Cans are their great strength, heavy coating of pure tin, and fine finish. They do not rust like common cans, have no crevices inside, will not leak, and need no repairs. No other cans have the Genuine Heisey Side Handles.

Look for the Milk Can Trademark.

This Can has 3 welded, tinned, wrought-iron hoops, tinned malleable side handles, and heavy XXXX genuine Cookley K cylinders.

Capacity 15, 20, 30, 40 and 50 gallons.

Refuse imitations. We make all patterns and sizes of Milk Cans, and will gladly mail you our hand-book free.

We Make Prompt Shipment.

JERSEY CATTLE SALE.

Kirkmont Herd At Auction!

TUESDAY, JUNE 6th, 1899,

Commencing at 1 p. m., at the residence MARSHALL M. KIRKMAN,

Corner Ridge Avenue and Lake St., EVANSTON, Cook Co., Illinois.

(Four miles north of Chicago.)

The Herd is made up of 22 members of the Stoke Pogis family and 15 of the Stoke Pogis-Landseer families, and has been built up with the one object of developing a TYPICAL DAIRY COW.

It consists of 24 Cows and Heifers. The service bulls, **IDA'S RIOTER OF ST. LAMBERT 24th** and **AARON'S RODNEY,** represent the choicest Stoke Pogis blood, and, therefore the highest type of Jersey. Every animal is registered in the American Jersey Cattle Club. The young bulls that will be offered are sired by the service bulls and are from the cows offered. They are worthy to head any dairy herd. Every cow in the list is a good breeder, gentle, a persistent milker and will make 4.5% test in butter fat. The Heifers are splendidly bred (from the sires and dams to be sold) and give every assurance of making choice cows. The herd will not be fitted up for sale, but will be offered on its merits as one of the best in the world. Each animal is guaranteed free from tuberculosis, and is subject to transfer in the American Jersey Cattle Club.

MARSHALL M. KIRKMAN,

TERMS CASH, or 30-day bankable paper. 1429 Ridge Ave., EVANSTON, ILL.

Cedar Hill Dairy Notes.

Chickens.—Silos.—Ice-houses.

ED. HOARD'S DAIRYMAN:—Well, they came! The chickens I spoke of in my last letter, 248 of them, about half and half Plymouth Rock and Single Comb Leghorns, and are now comfortably situated in our brooder house. This brooder house is, we think, one of the best to be found in Northern Ill., it is 30 feet long and 12 feet wide, is built of ship lap for outside wall and bricked between studding; roof shingled over tarred paper and 1 inch sheeting layers close together.

Heat comes from a hot water boiler and pipes; pipes run through 8 hovers, these hovers will mother 600 chicks up to 3 weeks of age.

To raise chickens in this way is more fun than running for office and don't cost as much. Last week's letter found us with 3 rooms in our creamery; this week we are starting to build the fourth one. This room is for our engine, bone cutter, feed cooker, etc.

We will conduct power from engine to ensilage cutter, a distance of 70 feet with a two-inch shaft. Our cutter will be the latest improved Ross, 16-inch knives, and will cut silage to fill two silos.

One silo is octagonal, holds 150 tons; the other (to be built at once) will be staves, round, and 30 feet deep, 5 feet underground and 25 feet above. The DAIRYMAN'S last silo plans hits our case exactly. As to manner of construction, we have corresponded with silo manufacturers and the prices they ask for knock down silos will almost knock down a would-be purchaser.

Our staves will cost us less than $80., hoops $12. to $15. It is so hard to make people believe but that a silo must be put up at a large outlay of money to insure its being good. It is the same as ice-houses and refrigerators were 25 years ago, a sort of mysterious method that but few dared to undertake.

My father followed dairying for a good many years in Waukesha Co., Wis., without ice, because he thought a house to keep it well would cost too much. I never have yet been where a silo could not be built cheaply.

Away up in the mountain parks of Colorado, 7,600 feet above sea level, where no stone or brick can be got, and other material high, I found that cedar poles set in ground in rows, for outside walls to be boarded against, was just as effectual as any way.

I believe a sod silo in the Dakotas would be as good as stone or brick, better in that locality on account of keeping out the severe freezes; just so we keep before us the idea of air tight walls coupled with proper strength. "BUFF JERSEY."

Dysentery in Calves and Other Young Animals.

[*Press Bulletin*]

Letters of inquiry to the veterinary department, regarding this disease, have, during the past month or more, been so numerous, and are continuing to come in at such a rate that it has been thought best to give to the public, through the press, a few of the best-known facts regarding this extremely fatal disease.

NATURE, OCCURRENCE AND CAUSE.

Dysentery in young animals is most frequently met with in calves, but also causes untold losses in pigs, lambs and foals, and is common in dogs and cats. That a similar disease occurs in human beings is a well-known fact. This disease is so common in many localities, becoming more prevalent from year to year, that in some places the growing of young stock must be abandoned. According to Roell, dysentery is so prevalent in portions of Austria that, in one herd of 3,318 calves, 1,196 animals were attacked and 1,152 died (97%). This gives an idea of the mortality to be expected from this disease.

The disease attacks, chiefly, animals from 1 to 4 days old; after that age it is a much rarer occurrence. Often the animals become attacked immediately after birth, without previously having taken any food whatever. This seems to prove that the milk of the dam cannot be considered as a factor in producing the disease. A further proof to this effect seems to be the fact that the feeding of milk from stables free from this disease is no hindrance to its development.

Although the infectious principle is not known, there is no doubt that the disease is infectious, and that the excrements harbor the infectious principle and constitute the chief medium for its dissemination.

It seems that the disease can be transmitted, not only from animal to animal of the same species, but also to animals of different species, e. g., from calves to lambs and pigs (Kotelmann). Friedberger and Froehner mention the fact that infectious abortion and infectious scours (dysentery) often occur at the same time and thus seem to have something in common.

SYMPTOMS.

The symptoms in different species of animals are much the same, and are only too well know by some cattle men. In calves we find the following: Loss of appetite, diarrhœa (very soft or even watery evacuations), restlessness, tenesmus (ineffectual straining to pass dung), and cries of distress Later, the excrements, which at first are of a gruel-like consistence, and of a yellowish color, become watery and whitish in color, mixed with mucus and particles of coagulated milk and even blood. At this stage the excrements have a most disagreeably fetid odor. Finally, involuntary evacuations take place, the animals become weak and lie down continually, have cramps and spasms, and discharge saliva from the mouth. The eyes become sunken, the hair rough, and general indications of emaciation can be observed.

Death may occur within twenty-four hours of the appearance of the first symptoms, but as a rule not until the lapse of two or three days. The mortality is very high (80 to 100% of all attacked animals die.) Frequently every calf in a stable will succumb to the disease. When animals recover they remain weak and unthrifty for a long time.

The symptoms in lambs and colts are much the same as those given for calves. A few other diseases, which may be confounded with dysentery, are sometimes met with, but careful observation, and the consideration of all facts presented, will guard against a false diagnosis.

TREATMENT.

Our greatest, and I might say, our only hope, lies in prevention. Prevention consists in the isolation of the healthy and the diseased animals, and in the thorough disinfection (see Bulletin 79, Bovine Tuberculosis, pp. 99-101,) Kansas State Agricultural College,) of the infected stables, yards and pens, as well as disinfection of the female genital organs (before and after parturition.)

The isolation of pregnant cows and their removal to new, or thoroughly disinfected, old quarters, a week or ten days before parturition, is an excellent plan. This is more rational treatment, and promises better success than any amount of drugs and medicine administered internally. Animals already attacked may be treated as follows: Give calves two or three tablespoonfuls of castor oil, lambs as many teaspoonfuls. Colts may be given one to three grains of calomel three times a day. The calomel, after being triturated with a little sugar, may be added to a little milk and fed to the colt. On the following day, or after the oil (or calomel) has had its effect (laxative,) the following recommended by Friedberger and Froehner, may be given: Powdered rhubarb root, 1 dram; powdered magnesium carbonate, 15 grains; powdered opium, 30 grains; good brandy or whisky, 2 ounces. Mix, dilute with equal parts of water, shake well, and give to calf as one dose, repeating a similar dose every three to six hours until the diarrhœa is relieved.

In the same manner, colts may be given 1 to 2½ drams of tincture of opium, lambs 30 to 60 drops, repeating the dose, as above, every three to six hours until relieved.

The following treatment was used with success by the author: Take wood tar, one pound, place in a vessel and pour over it three gallons of boiling water; allow to cool, and pour off the straw colored liquid (tar water,) which is used as follows: As soon as the calf shows symptoms of diarrhœa, inject, with a syringe, one-fouth pint of this liquid into the rectum. Repeat the operation every half hour. Use a hard rubber syringe, with a long nozzle, oiling it, if necessary, to facilitate its insertion, and to prevent possible injury. Next day continue this treatment, and, in addition, dilute all milk fed to the calf with one-fourth its bulk of this tar water. Keep this up until recovery sets in. With this, as well as with any other treatment, the most important thing must not be neglected, viz, providing for the tender young animal's comfort. Provide a clean, comfortable stable, plenty of fresh bedding, which must be renewed every day, pure air, light, quiet surroundings and gentle treatment. If the animal is allowed to suck, wash teats of dam with a 3% creolin solution (tablespoonful creolin to one pint of water) immediately before. If calf is fed by hand, wash your hands in hot soap water, using a stiff brush, and then rinse them in 3% creolin solution. Keep pails and all utensils, with which milk is handled, scrupulously clean by means of frequent scalding. Disinfect stables and yards frequently with a one-fifth per cent solution of bichloride of mercury.

Pregnant cows should be treated as follows: A week or ten days before they are due to calve, isolate them and inject (gently) one-half pint of a 3% creoline solution into the vagina. Repeat this operation every day until the calf is born. After the calf is born inject half a gallon of this solution into the uterus, repeating the operation once daily for three or four days, or until all unnatural discharges cease.

All this means strict attention, study, work, and a little expense, but without these do not expect or even hope for success.

PAUL FISCHER.

Kansas Experimental Station.

For Preserving Milk Samples.

ED. HOARD'S DAIRYMAN:—I would suggest to "Subscriber" that he use Stewarts tablets to preserve his samples of milk, instead of bichromate of potash. The "tablets" are corrosive sublimate, and there is no danger of using too much, so as to affect the result with the Babcock test.

I have made several tests with both; once used an overdose to see if either would cause a poor test. With the tablets, I have used as high as three in half a gill of milk and had just as clear a reading as when using a half of one. With the bichromate, a little too much would not give a clear test, and with a large overdose I could not get a reading that was at all satisfactory.

In my samples I use a half pint bottle, taking not more than a large teaspoonful each day for two weeks, using a half tablet in each bottle.

I do not want the bottle over half full at the end of the two weeks, as I can get the cream that adheres to sides of bottle, off better than when it comes up well toward the top.

I find I get better results with my milk colder than the acid at time of making the test. This can be done by setting the test bottle in ice water as soon as filled, and leaving them until ready to add the acid.

Riverton, Mich. B. T. T.

Sauerkraut as an Appetizer.

Best Thing in the World for a Sick Cow.

A reporter who spent Christmas among the Pennsylvania Germans of Lancaster county, discovered what will probably be to most people a distinctively new use for sauerkraut, a native production of old Lancaster and a staple article of food, says the *Pittsburg Times*. He had called to see an old friend who keeps a dairy, and found the dairyman in the act of taking great bunches of succulent cabbage from a barrel in the cellar. The odor pervaded the neighborhood and made glad the nostrils of every true and loyal Pennsylvania "Dutchman," within a distance of about half a mile. The reporter was astonished when the dairyman picked up a bucketful of sauerkraut and carried it to his cow stables. The second animal in the long row of stalls was a big, strong-boned cow. Her head was hanging low under the manger, although there was a plentiful supply of hay in the rack above. Her ears had a dejected droop, and her eyes were half closed. She was evidently a very sick cow at a time when she should have been in good spirits, for among the Pennsylvania Germans it is still a popular belief that on Christmas eve the cows in their stalls may be heard to talk to each other of the great event the day commemorates. The bucketful of sauerkraut was dumped into the manger. The cow, by some peculiar system of feeding, first gave evidence of her appreciation by slowly switching her tail, which had before hung limp and lifeless. Then she raised her head, poked her great muzzle into the kraut and slowly began to munch the stuff. Fifteen minutes later she looked quite happy She had eaten all the kraut, and was taking great mouthfuls of the hay. The dairyman said sauerkraut had long been known as one of the best things in the world to give a sick cow an appetite.

ROUND SILOS

LABOR 1-2 SAVED.

Also best Horse-power, Thresher, Clover-huller, Dog-power, Rye Thresher and Binder, Fanning-mill, Feed-mill, Saw machine (circular and drag), Land-roller Steam engine, Ensilage and fodder-cutter, Shredder, Root-cutter and Corn-sheller.

A PIANO AT A NOMINAL PRICE

Chicago's largest music house, Lyon & Healy, to sharply reduce stock is offering sample new uprights, slightly used pianos and secondhand instruments, at almost nominal prices. Good, durable uprights as low as $100, warranted as represented. Square pianos $20 and upward. Grands from $200. Send for complete list just issued. Among the makers are: Decker Bros., Hardman, Knabe, Steinway, Weber, Hale, Bauer, Fischer, Hazelton, and others. If you are interested in a piano, do not fail to write at once, as this opportunity may not soon occur again. Any piano not proving exactly as represented may be returned at their expense.

PARAFFINE BUTTER.

Unless a halt is called we shall have the Standard Oil Co. including the manufacture of butter (?) among their other numerous products.

From the view of the adulterator of food products, paraffine is an ideal substance to mix with and improve butter. It is tasteless, odorless and cheap. There is a chance for a big profit in selling paraffine that costs five cents per pound for butter that is worth twenty.

It matters but little that paraffine is indigestible, insoluble and absolutely worthless as a food. It can be mixed with other fats, colored, salted and sold to the poor, who cannot afford high priced butter, and the millionaire who prefers oleo, (according to the testimony given in Chicago), and then be filling a long felt want of both consumer and producer.

It will increase the value of every barrel of petroleum produced and also the value of Standard Oil stock at the same time.

The butter (?) will keep in any climate and under any conditions. Its many advantages are numerous when compared with butter made from cream. Incidentally it will destroy the dairy interests of the country, but of course that need not enter as a factor into the plans of the manufacturer of paraffine butter; that is a condition that can be considered when the production of the petroleum article is well established.

Dairy cows will be cheap then and plans can be formed to manufacture embalmed roast beef from them. In themean time, what do the dairymen of the country think of the outlook?

Warm Barns.

ED. HOARD'S DAIRYMAN:—I noticed an error in last week's DAIRYMAN in recording the Guernsey transfers. King Samm, No. 5865, from A. J. Philips to Geo. C. Hill and Son, of Rosendale, Wis., should read to Geo. C. Hicks and Son, of Battle Creek, Mich. In your comments on the article I wrote on the high temperature of the barn, I accept your amendment, and am aware that the machinery and working parts of the cow, are like the Texas story, they are fearfully and wonderfully made.

I did not mean to recommend that a stable should be kept near blood heat, but the point I wanted to impress on northern dairymen, or cow owners' minds was, that an even temperature, that is easier kept well up, by continuous stabling and closed doors was productive of better production, better profits. Takes less feed and less expenditure of butterfat to keep the cow warm.

My experience and observation has taught me, that when there is one barn kept too warm or one cow too well fed and cared for, there are one hundred that reach the opposite extreme and I think 500 of the latter would be nearer the truth.

Nearly four weeks ago, I saw cows turned out into old pine choppings, trying to live and produce milk and cream where a mountain sheep or goat would have to work twelve hours a day to live. Hay was gone, no bran or other grain feed, and the owner said his returns from the creamery were so small he believed he would quit the business, and the cows looked as though they were ready to quit to.

I realize that God moves in a mysterious way, and I sometimes wonder if he has ever made a move to provide a heaven for men who ill treat and starve the useful cow and the faithful horse that he provided for their use. Kindness to dumb animals, is a great text to preach from. Success to the DAIRYMAN, in its missionary work among the farmers.

A. J. PHILIPS.

West Salem, May 15.

How and When the Surplus Make of Butter can be Exported to the Best Advantage.

ED. HOARD'S DAIRYMAN:—I think there are few but what will admit that the production of butter in this country is now greater than home consumption can take care of at anything like remunerative prices to its producers, and it appears to me as if, how and when the surplus make can be exported to the best advantage, to all interests, ought to now be carefully considered, seeing we are approaching the period of the flush of the make.

The seasons of 1897 and 1898 afford much information, and from which there is ample data to assist us in forming an opinion on the subject matter. These two seasons were somewhat similar in the matter of production, and they were normal. Prices in 1897 fell to 15 cents, in New York and Boston, during June, for extras in creameries; 13@14c, for seconds and firsts; 12@13c for extra imitation creamery and 10@11c for extra ladles. This enabled exporters to send liberal quantities of the product out of the country under the most favorable conditions, in so far as the matter of quality was concerned, American butter soon got a footing and reputation in all the foreign markets.

The quantity sent out of the country up to September 1st, was sufficient for all home markets to thereafter sustain a higher range of values the balance of the season, but it would have been better if prices had not advance in August, until about 100,000 packages more had been sent out, as home markets could have then sustained a still higher range of values for the balance of the season. The season was a good one to the butter trade generally, in this country and Great Britain.

There never had been before, a year when so much American butter was sold for table grades in England. The season of 1898 was almost diametrically opposite to that of 1897, in nearly every feature. Prices in June opened about 2 cents higher than in 1897, and they were kept so until the third week of August, which prevented exporters handling much of the better descriptions, and with little or no profit. What was the result? Home markets could not sustain as good prices after September, as they did in 1897, and in December it was clearly evident that it was absolutely necessary to bring on an export demand to prevent a disastrous wind-up this spring.

Unfortunately it was at a time Australian and New Zealand goods were arriving in England in immense quantities, all fresh made grass goods, and which our stale American goods had to come in competition with. It is true it gave the relief looked for to our home markets, but at the expense of our reputation in foreign markets, as much of that shipped were cold storage goods, which had deteriorated, more or less, from age. Most of these goods were sold at a loss to the owners of them at the time, and in many cases at no higher prices than shippers could and would have paid last summer, and when they were fresh and sweet. The June deal of 1898 was not a success, as all will have to admit.

If the two seasons of 1897 and 1898 teach us anything it is, that to make a June speculation at all successful, the product has got to be bought at very low prices, or else a large portion of the June make must be shipped out of the country to cause higher prices for that portion of it which is held in cold storage in this country. It is clear to me that until we greatly decrease the make of butter during the summer and increase the winter make proportionately, we must look for a low range of values during the flush of the make. Producers of butter should assist in every possible way the matter of exporting the surplus during the flush of the make, as by doing so the butter is out of the way and markets in good shape for their fall and winter production. Whereas, if they sell to speculators their summer make and the butter is held here, it is always a rope around the market's neck for their fall and winter goods, as speculators will bring their summer goods out at every stage of advance that may turn a profit.

It is foolish for one to forecast the probable course of markets, especially on such an article as butter, which weather conditions affect so greatly, but there is this to be said, and that is, the best foreign markets for our surplus are those of Great Britain, but, unfortunately for us, the product of the antipodes has assumed such colossal proportions, and yearly increasing, and is marketed in Great Britain between Nov. 15th and May 15th, it must be clear to all that our surplus must therefore be marketed abroad between June 1st and Oct. 31st in order to avoid its coming in competition with these goods from the antipodes.

The English working people are at the moment well employed and at good wages, and when in such a condition they are great consumers, especially so in the matter of butter when it can be purchased for 18@20c at retail. When butter can be sold at such prices, the consumption of margarine and mixtures is always greatly lessened and that of the real article greatly increased. It is therefore reasonably certain that with a normal condition of weather conditions and make on this side, that the English markets during June, July, August and September could take care of 300,000 to 400,000 pkgs. of all grades of our butter, if shipped promptly after being made, and at about a cost of 15@16c, f. o. b. steamers, to English importers, for extras in creameries, 14@15c for firsts, 13@14c for imitations and 11@12c for extra ladles.

It would be a great advantage to the industry generally, if ladles and imitation creameries could be exported largely during the summer months, as the better description of these goods could be used largely for a cheap table butter, while they are fresh and sweet. They cannot be used in this way after they are held in cold storage for months, as they grow bad after being removed from the influence of cold storage and invariably have to be used for a low grade of confectioner's butter in Europe.

It is unfortunate that the requirements of English markets in matter of package, and to some extent that of color and saltness, is so different to the general requirements of markets in this country. The finest grades of creamery, in the Australian box, natural grass color, or pale straw, and salted one-half ounce to five-eighths ounces to the pound is the most desirable and will bring from one-half to one cent a pound more in the English markets than the same quality of butter higher colored and higher salted and packed in the 60-pound ash tub.

Creamerymen will naturally be loath to put up their butter in these boxes, salted and colored as mentioned, as should there not be an export demand on our home, buyers would discriminate against these Australian boxes as badly as the English cutter discriminates against the 60-pound ash tub in favor of the box, so that it would be well for creamerymen not to put their butter up in this shape without first having some understanding regarding the matter of price.

However, the tendency in this country is to lighter salting and lighter coloring than what was in vogue two or three years ago, and butter put up to meet the requirements of the New York market, in matter of color and salt, is not too high in these two particulars for some of the English markets, but it must be remembered that any butters highly colored or highly salted are most undesirable for all English or Continental markets GEO. A. COCHRANE.

Boston, May 5th, 1899.

CONCERNING OUR ADVERTISERS.

P. J. Cogswell, Rochester, N. Y., writes: I have recently shipped the bull, Acte's Exile 54632, to Mr. John H. Garrison, South Easton, N. Y. Mr Garrison writes: "The bull came through all right. I like him very much. I think he will make a very fine animal."

Acte's Exile is a very fine solid lemon fawn son of Exile's Diadochus, having by him three tested dams. His dam, Exile's Acte, is a young daughter of Exile of St. Lambert 13657. She has never been tested, but is doing fine work, with a good prospect of being added to Exile's list. Her dam was Koffee's Duchess 2nd, (17 lbs. 1 oz.), who averaged 36 lbs. of milk per day for six months, and she a granddaughter of Ida's Rioter of St. Lambert. through Ida's Pogis.

If appearances count for anything, this young bull will make a sire that will be heard from, as he is well fitted by breeding and individuality.

AROUND THE WORLD IN A DAY.

This globe of ours is a pretty good sized sphere, but we are told the Deering Harvester Company of Chicago can produce in a single day enough Binder Twine to encircle it, with 3,500 miles to spare—30,000 miles of twine is a fair day's output! A reliable publication recently proved by correspondence with dealers in all parts of America that 36 per cent of the twine used in 1898 was Deering Twine.

FREE TO SUFFERERS.

The New Cure for Kidney, Bladder and Uric Acid Troubles.

Almost everybody who reads the newspapers is sure to know of the wonderful cures made by Dr. Kilmer's Swamp-Root, the great kidney remedy.

It is the great medical triumph of the nineteenth century; discovered after years of scientific research by Dr. Kilmer, the eminent kidney and bladder specialist, and is wonderfully successful in promptly curing kidney, liver, bladder and uric acid troubles.

Swamp Root has been tested in so many ways, in hospital work, in private practice, among the helpless too poor to purchase relief, and has proved so successful in every case that a special arrangement has been made by which all readers of HOARD'S DAIRYMAN who have not already tried it, may have a sample bottle sent free by mail, also a book telling more about Swamp-Root and how to find out if you have kidney or bladder trouble. When you write mention reading this generous offer in HOARD'S DAIRYMAN and send your address to Dr. Kilmer & Co., Binghamton, N. Y. The regular fifty cent and one dollar sizes are sold by all first-class druggists.

CANCER cured at home. Send four cents, stamps. 80 page book, illustrated Dr. J. B. HARRIS, 2226 Kemper Lane, Walnut Hills Cincinnati, O.

SCHMIDT'S Treatment for Milk Fever

The new remedy that has a record of 90% of cures in 412 cases. Two complete treatments with full directions and necessary apparatus neatly packed in a box for shipment, Price $2.75. Every dairyman should have this outfit on hand ready for instant use Order at once from GARDINER BROS., 220 E. Preston St., Baltimore, Md.

ABORTION!

Retention of Placenta and Failure to Breed.

H. W. KELLOGG'S experience with and positive cure for these diseases in cows. Send for circulars. Address all communications to H. W. KELLOGG COMPANY, Ripon, Wis

LONG GREEN, Feb. 12, 1898.

H. W. KELLOGG CO.,

DEAR SIRS;—Enclose please find nine ($9) dollars for which please send by express 25 lbs. of your Abortion Cure. We tried the 2 lbs. of Nov. 16 and both cows came out all right and we have much faith in it. Please send immediately. Yours,

A. B. SMITH,
Long Green, Md.

ANTIABORSIO.

WILL PREVENT ABORTION in cows and cure scours in calves. One gallon will treat twenty cows three months.

Our Specific No. 1: Absolutely prevents Hog Cholera and Swine Plague, and will cure 90 per cent. of sick hogs

Our Specific No. 2: Prevents and cures Roup and Gapes, and kills Vermin on Poultry, also kills Ticks on Sheep. These are established facts, not experiments.

Our remedies are liquid germicides applied by sprinkling in closed stables and pens. Cures by inhaling fumes which destroy the germs of disease.

Send for free booklet and testimonials.

Animal Germicide Co., 319 Washington St., N. Y

Dr. Horne's Anti-Abortient

Prevents Abortion and cures Nymphomania—failure to breed; also Emmenagogue Powders for cows failing to come in heat. Both powders are the result of long practical experience and study and may be given in a little moist feed. 5 oz. $1, 11 oz. $2, 23 oz. $4, 50 oz. $8, by mail.

Also Specific for

SOUTHERN CLIMATIC FEVER

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

Dr. WM. HORNE, Janesville, Wis.

ALDERNEY BUTTER COLOR

Buttermakers using it say it gives perfect satisfaction in every respect and recommend it to all not using it.

Manufactured by THE HELLER & MERZ CO., Office, 55 Maiden Lane, N. Y.

BRANCHES:—Chicago, 14 No. Clark St.; Boston, 98 Commercial St.; Philadelphia, 109 South 2nd St.

Some of the alleged provision papers are making a great hue and cry over the injury the recent developments in the beef inquiry are likely to work in our export meat trade. One of them brings forth a labored argument to prove the value of boric acid as a meat preservative; yet we have been solemnly assured, times without number, that no chemicals are used by the packers. Why this argument? If our meat trade is injured in this way, who is responsible, the men who tell the truth about the business, or those who used the stuff? And if this chemical is so harmless, why will it injure our meat trade abroad to have it known that our packers use it?—*Rural New-Yorker.*

And it is these same packers who manufacture the much lauded and long-keeping oleomargarine. What is it that causes this product to keep so well?

Butter and Butterfat.

At a farmers' institute held in Paw Paw recently, the questions were discussed why milk would churn more than the Babcock test showed, or why creameries had an increase or overrun. It seems that the discussion upon the subject at this meeting failed to make it satisfactory, and I have been asked to make a little explanation on this point through this paper.

Butter is composed of four principal parts, namely: Butterfat, casein, salt and water. A pound of butter ordinarily contains 12 to 15 per cent of other ingredients than butterfat. I have said that the ordinary increase was from 12 to 15 per cent, but this increase will vary both ways from the general rule.

The next question that would naturally arise is, why is this the case? There are many things to cause this variation, and I shall mention the principal ones. The main causes are:

1. The kind of separator used and the way it is handled.

2. The condition of the milk when skimmed. What I mean by condition of milk is whether or not the milk is perfectly sweet and fresh.

3. The nearness to complete exhaustion of cream in churning.

4. The kind and quality of salt used.

5. The amount of casein and moisture left in the butter, which varies somewhat with the season.

6. The time of year itself.

What I mean by the time of year is this: For example, a factory has 6,000 pounds of milk per day at the beginning of August. By the last of the month it is only getting 3,000 pounds per day. The quantity of milk having decreased, the quality having improved just a little, and the milk being generally a little off, it quite often runs the increase down to nothing and I have known cases where there was not as much butter made as the Babcock test called for.

Most people, when reckoning up how many pounds of butter are made from 100 pounds of milk, fail to add the overrun, which, in all co-operative creameries in this part of the state, they have credit for. For example, if a man has a test of 4 per cent and there was a 12 per cent increase, by adding 12 per cent of the test to itself he would find the number of pounds per cwt. that his milk made, and for which he actually had credit. If a man's milk test 4 per cent fat and there is an increase of 12 per cent, his milk makes 4.48 pounds per cwt. or nearly 4½ per cent. E. D. HULL, Glendale, Mich.—*Northener.*

THE FAMOUS DARLINGTON FARM AND DAIRY.

Thirty-four years ago the coming month, the editor of this paper, then a federal soldier, paid a visit to the famous Darlington dairy farm in Chester Co., Pa. The butter from this renowned dairy was then selling at a dollar a pound. The following extract from a description of the farm and its appurtenances is taken from the West Chester *Republican*:

A typical farm of this class, and one among the most successful of them is that of the Darlingtons, at Darlington station on the Media railroad. The present owners, Jesse and Alfred, are men past middle age, and their father was famous as a dairyman before them. They command 850 acres, mostly of the rich meadows lying along the graceful wanderings of Chester creek, and churn the milk of 250 to 300 cows. Half a mile from the station, southward, the farm has its own creamery, fitted with every convenience, but it is the knowledge and skill of the men who use these appliances, and not the conveniences themselves, which are responsible for the high grade of the product.

It has been said above that good dairymen begin with the cow and the field. Every cow that is added to this herd, whether raised or purchased, is thoroughly tested. A record of milk yield is kept, and the percentage of cream ascertained by a curious little machine driven at a high speed, which separates cream from milk in a sample bottle. In this way the exact butter yield of a new cow is ascertained throughout the season, and if she proves satisfactory she is retained, otherwise she goes out to market. The milk averages perhaps 4 per cent, but a free milker at a fraction less is held more valuable than one with a higher percentage and a scanty flow. Such a cow properly fed to her healthy limit, on the right kind of food, will make good butter and enough of it to leave a profit at the end of the year. Green food is an essential to good feeding, and the Darlingtons, after watching carefully and experimenting for themselves, are firm advocates of the silo, which they have long had in practical use.

Twice a day the milk, warm from the cows, is run through the centrifugal separators, of which they have two. The cream comes out at a temperature of about 88 degrees, and passes at once through a cooler where a steady flow of water from a never failing spring in the building reduces it promptly to 57 or 58 degrees. No ripening ferment is used; the cream being set in deep cans in this spring water, which does not vary more than a degree or two from fifty the year around, and after thirty-six hours it goes to the churn. A ten-horse engine drives this and the other machinery; and the butter, after coming from the churn, is worked by the oscillation of a corrugated cylinder on a table, driven by the same power. After reworking and salting it is made into pats, and goes to the refrigerator. At shipping time it is brought out on plate glass shelves, each roll is wrapped in cold wetted clothes, it is carefully packed in tubs and taken to the station in time to make close connection with the requisite train.

The refrigerator is kept at the required temperature by a miniature ice-making machine, a model of the one told of yesterday in an account of the cold storage plant. A brine tank occupies the top of the butter closet, and the ammonia pipes circulate through it. A short time running the pump is sufficient to reduce the mercury to nearly or quite zero, and the refrigerator will keep this over night without rising to the thirty-two degrees. A sloping semi-roof over the butter throws the air chilled by the bottom of the tank down to one side of the closet, the warmer air rising on the other side, and leaving its moisture on the surface of the cold brine. This circulation insures dryness, so that a wet cloth hung inside at night will be absolutely dry on opening in the morning.

The milk used at this creamery is exclusively their own. To maintain the standard set for this butter it is absolutely necessary that they know what feed the cow has and what she does not have; it is necessary to know that absolute cleanliness obtains about the milking stalls, that neither dust nor odors shall have opportunity to add their undesirable qualities to the product. They must be kept out, for once admitted to the milk no process has ever been invented for separating them again from the true butter flavor. It would be manifestly impossible to maintain this close supervision if milk were bought.

The secret of their fame as butter makers is simple in the stating, but difficult in the carrying out. It lies in profitable cows, intelligent feeding, cleanliness, adequate apparatus and monotonous method even in smallest details. Always the same thing at the same time in the same way; that makes always the same butter and always the same price. It is the monotony of it that pays.

Farm Wagon for Only $19.95.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, sold at the low price of $19.95. The wagon is only 25 inches high, fitted with 24 and 30 inch wheels with 4 inch tire.

This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Co., Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

Cured His Rupture.

AFTER SUFFERING FIFTEEN YEARS A MAINE CITIZEN RECOVERS.

Remarkable Discovery of a New Healing System.

People who have been ruptured for some years generally settled down to the notion that they must end their lives in suffering. Usually, they have tested all sorts of cures and trusses and give

MR. WALTER J. COLBY. Brunswick, Me.

up at last in despair. But now comes a new plan a radically different system which says positively that any kind of a rupture, old or recent, bad or slight can be cured completely and permanently in a very short time. The experience of Mr. Colby is cited as an evidence of what the new plan will accomplish. Mr. Colby was badly ruptured. For fifteen years he lived in constant dread of strangulation. He tried everything known in the truss line and still his rupture was there just as it had been for fifteen years, worse if anything. Some one called his attention to the so-called Dr. Rice system but he was skeptical. He sent for an explanation of the plan and this so appealed to his experience and sense of the fitness of things that he could not resist the impulse to try it, skeptical as he was.

The results have more than met expectations for not only was his severe rupture returned into the abdomen and securely held there but the cure was absolutely perfect and permanent enabling him in a few short weeks to do any kind of work without fatigue, bother or feeling that he had ever been ruptured. It is a home cure. No pain nor danger can possibly happen. A person won't lose a moment from work. There is no operation of any kind and the plan is so certain to cure, that every ruptured person ought to know all about it. Dr. Rice has prepared an illustrated book telling about his discovery in a most convincing manner. He sends the book free to all. Write for it. If you know others who are ruptured tell them to write for this free book, or do so yourself. It will be an act of kindness which they will appreciate. Write to Dr. W. S. Rice, 353 C. Main St., Adams, N. Y.

LUMP JAW

Easily and thoroughly cured. New, common-sense method, not expensive. No cure, no pay. FREE. A practical, illustrated treatise on the absolute cure of Lump Jaw, free to readers of this paper.

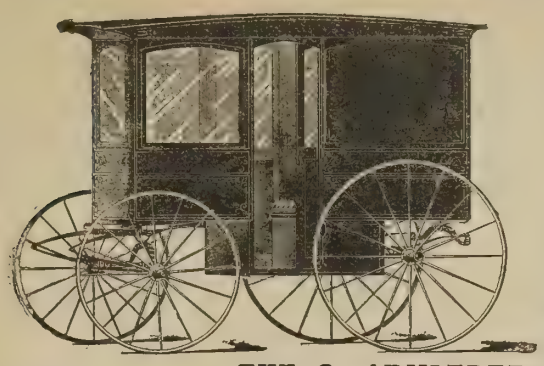
Gluten Feed

is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.



Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it.

Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating "Value of Butter Fat in Milk," all FREE if you address

A Perfect Milk Wagon

On a Perfect . . .

Short Turning Gear

We make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue which fully illustrates and describes this wagon and 10 other styles.

THE NEW BOOK

Feeds and Feeding

By Prof. W. A. HENRY.

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

or

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

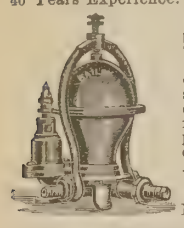
"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be refered to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price $2.

Potash.

ENOUGH of it must be contained in fertilizers, otherwise failure will surely result. See that it is there.



Our books tell all about fertilizers. They are sent *free* to all farmers applying for them.

Durable--Effective--Economical.

OSWEGO FALLS, N. Y., April 25th, 1899.

P. M. SHARPLES,
West Chester, Pa.

Dear Sir:—It is now one year since we put in the No. 25 Tubular Separator. It has not cost one cent for repairs and runs just the same as when first put in. It does fine work and gives the best of satisfaction.

The ease with which we can change from light to heavy cream makes it of especial value to us, for we ship three grades of cream, and must therefore make both light and heavy cream most every day. When we need more separators we will buy only Tubulars.

Thanking you for your courtesy in the past, Respectfully,
E. M. RICHMOND, Manager,
Fulton Dairy Co., JOHN HART, Prop.

JOHN HART is one of the Greater New York's best known milk handlers. He handles large quantities of commercial cream, which must be smooth and uniform to suit his trade.

THE SHARPLES TUBULAR SEPARATOR

fully answers this requirement and it will yours.

The cleanest of rapid skimmers.
The simplest in construction.
The most durable and economical.

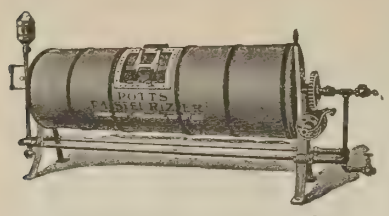
Grade up Your Herd..

The expense of feeding a profitable cow is no more than the cost of feeding an unprofitable one.

It costs comparatively nothing to find out whether each member of the herd is profitable. The



NO-TIN... Babcock Tester

will give exact information. Is substantially built of cast iron, and made to use the ordinary Babcock bottles.

TEST EVERY COW and if she is not profitable, do not keep her. It is the best low priced tester in the world. Send for Catalogue, No. 71.

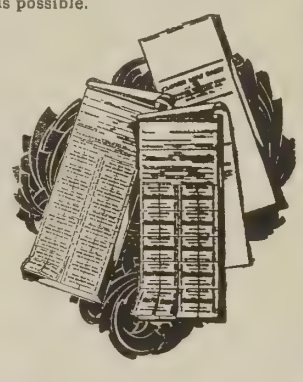
Elgin Manufacturing Co., Elgin, Ills.

Pasteurization

Of milk and cream has passed the experimental stage, and is now an absolute necessity for all UP-TO-DATE and well regulated Milk Depots that wish to supply a perfectly healthful food, free from all disease germs, and one that will keep sweet without the use of chemical adulterations.

It is an established fact that pasteurized milk and cream will keep sweet from ten days to two weeks without the use of ice, and still have its consistency. Potts Pasteurizer insures against cooked flavor, and, if operated according to directions, cream will rise on the pasteurized milk just as quickly and as well as on milk that is unpasteurized.

The Expense of Pasteurizing in



Potts Pasteurizer

Does Not Exceed ONE CENT PER GALLON, Taking EVERYTHING Into Consideration.

There is no other pasteurizer on the market that will give the results and do the work of the Potts. We refer to the Wisconsin Experimental Station, of Madison, Wis., for the confirmation of this statement, and if you desire can furnish you with a large number of names of other parties using these machines to their entire satisfaction.

If you are contemplating buying a Pasteurizer, please do not purchase until you have corresponded with us. We will be pleased to send you special circular matter, and a so endeavor to have one of our special Pasteurizer representatives call upon you if it is possible.

If you have ever thought of buying a thoroughly complete **Milk Dealers' Outfit,** we are positive that we can give you valuable information, and in the way of circular matter, describe a full line of utensils and supplies that are necessary for operating a thoroughly up-to date plant.

Our new **Incised Keystone Brand Caps, Ideal Steam Turbine Bottle Washer, Sanitary Milk and Cream Tickets, Signs and Placards** of all descriptions, as well as a complete list of **Milk Dealers' Stationery,** including Letter Heads, Statements, etc., etc., **Bottle Washing and Filling Outfits,** and an innumerable list of new and convenient articles that have been used by all the larger aggressive dealers with the very best results. We will be pleased to send you circulars descriptive of these articles, as well as samples, and ask that you communicate with us for further information.

The Ever Increasing Demand for

The Improved U. S. Separator

shows conclusively that Dairymen appreciate the worth of this machine. The sales were never so enormous as at present. To give those who are not familiar with its superior qualities some idea of what users think of it will add a few sample letters.

What the President Says.

BRATTLEBORO, VT., Feb. 27th, 1899.

It gives me pleasure to say that the dairy machinery bought of your company two years ago, including a No. 5 Improved U. S. Separator and a Pony Power, is working well and giving entire satisfaction.

The Improved U. S. Separator is doing all and even more than was claimed by your agent. The **separation is perfect,** it runs easily, without noise or friction, and it is easy to manage and care for. Of all the separators placed upon the market, there is none that excels the Improved U. S. in my opinion.

G. W. PIERCE, President Vt. Dairymen's Ass'n.

30 Per Cent. More Butter and of Better Quality.

OTIS, IND., October 4th, 1898.

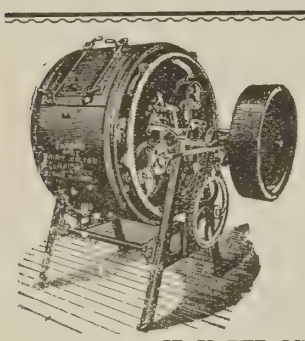
The Improved U. S. Separator purchased of you has exceeded my highest expectations. In simplicity of construction and ease of running it cannot be beat. It has given us no trouble, and we have made from the start 30 per cent. more butter and that of a better quality than we did previous to obtaining the U. S.

Hoping the Improved U. S. will continue to lead, I am, etc.,
HENRY STORMES.

Excels All Others.

COLDWATER, N. Y., June 28th, 1898.

The Improved U. S. Separator is in constant use and is giving perfect satisfaction. I can say from actual experience that in ease of running, **close skimming** and quality and quantity of cream produced it excels all others. No farmer or dairyman can afford to be without one. They will pay for themselves.
C. C. BEAMAN.



Superior to Anything in Cream Separator Line.

BORDER PLAINS, IOWA, Aug. 15th, 1898.

I bought an Improved U. S. Separator this spring, and therefore have had ample time to test and also to compare it with other machines. I think the Improved U. S. is superior to anything in the line of cream separators I ever saw. For simplicity, ease of operation, thoroughness of work and substantial appearance I can recommend the U. S. I think it is O. K.

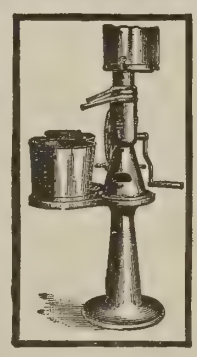
VERMONT FARM MACHINE CO., Bellows Falls, Vt.



THE DAIRY "VICTOR" Churn.

This Combined Churn and Butter Worker is proving itself to be precisely what the farmers and dairymen have been seeking after. It's work is as complete as the work of the "Factory" Victor Churn, which is rapidly supplanting every other Combined Churn and Butter Worker.

IT IS THE ONLY SUCCESSFUL DAIRY COMBINED CHURN AND BUTTER WORKER ON THE MARKET.

It is easy to handle, easy to clean, perfect in its work, durable and reliable. It charms every farmer and dairyman who sees it work. Manufactured by . . .

F. B. FARGO & CO., Lake Mills, Wis.

A Hand Separator

to be profitable must not only extract every particle of butter-fat from the milk, but must run so easily that it does not require the strength of a giant to turn it. We guarantee the

Empire Cream Separators

to run 50 per cent. easier than others of equal capacity. Their record for clean skimming is unequalled. We have the most complete line of hand separators in America; also power machines.

We have not space here to tell you why the **Empire** machines excel all others, but it's all in our catalogue. Send your address if you have one cow or one thousand.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

WHICH IS THE BETTER COW?

We have received a goodly number of answers to the above inquiry which was printed in the DAIRYMAN of May 5th, in connection with the pictures of two Guernsey cows, and very much as we expected, Rose of the Quartiers appears to be the favorite. We were not prepared, however, to see her take so strong a lead as 8 to 1, which is the proportion of the replies in her favor.

Republishing the pictures herewith, we print below several of the letters received, omitting and condensing as much as possible and preserve the general sense. It would be hardly fair for us to give any personal comment, inasmuch as a letter was received from the Superintendent of Mr. Morton's herd very soon after the pictures were published giving the records of these cows, and in the nature of things would more or less effect one's conclusions, where appearances are so evenly balanced. We do not consider it at all certain that these cows may not reverse these records another year:

T. B. MILLAR, ONTARIO.

I consider Rose of the Quartiers the better cow.

1. Eyes bright and prominent.
2. Plenty of heart room.
3. Large digestive capacity.
4. Well developed udder.
5. Milk veins large, extending well to front, and from what I can gather from the cut, I think that she has the wedge shape fairly well developed. I think that "Villet's Gem" lacks depth of body, and digestive power would not stand forcing.

I will watch with pleasure for the report of this judging which I consider excellent practice for young dairymen like myself.

H. A. DEAN, ARKANSAS.

The reasons for thinking Rose is the better cow are, she is more wedge shaped than the other, a little higher in the flank, and deeper down through the body; not so high up on legs. The cows we milk that are the nearest perfect in the points named are the best, but pictures are pictures, and on seeing the cows one might change his mind.

H. A. BREIHAN, TEXAS.

Rose of the Quartiers has the advantage of Villet's Gem, in the front two-thirds, her bright face, ewe neck, and light withers in first; and greater depth in second third. In the last third I see no marked difference. Rose of the Quartiers has the better double wedge form; no doubt they are both good cows.

C. E. BULL, COLORADO.

Rose of Quartiers is the better cow:

1. Because of her greater depth of barrel indicating greater digestive powers.
2. More prominent milk veins.
3. The extension of udder, both forward, denoting longer lactating period, and so well up in the rear, indicating capacity to carry milk.
4. More massive and bony hips, which show greater strength.
5. Fullness of the eye, and high pelvic arch indicate a greater percentage of butter fat.

Z. M. WATERS JR, MARYLAND.

I think it hard to judge which is the better cow of the two. I would judge that Rose

VILLET'S GEM, A. G. C. C. 8664.

was the heavier milker. She has better shape of udder as it is not cut off in front quite as much and her milk veins are more prominent. She also has a deeper barrel, and in general looks like a heartier cow.

Villet's Gem has a more prominent navel, and I like her tail, neck and head better than I do Rose's. I would not be afraid to buy either for a first-class dairy cow.

JOHN W. VAUGHN, CALIFORNIA.

I have chosen Rose of the Quartiers for the following reasons: First, she is better in

ROSE OF THE QUARTIERS, A. G. C. C. 8654.

the muzzel, greater lung and heart capacity, also larger food capacity, wider pelvis, more decided arch and incurving thighs and seemingly more marked escutcheon and larger udder.

CHARLES F. ROY, VIRGINIA.

Rose's head is short and square, eyes large and prominent, nostrils wide, muzzle fine and slightly turned up; lips small and regular, horns fine and medium; chest wide and deep, well carried forward. I prefer Rose because her dewlap is better shaped, her front legs straight and more sloping inwards, (knock kneed) her neck finer, her withers sharper, her spine straighter and more level, her barrel larger, deeper from hip bone down, her hip broader and her pelvic arch is better shaped, her udder extends better in front and higher behind, her croup stands neither too high nor too low, her tail is well set on, thick at the root and slender at the switch, her thighs low and muscular.

W. T. NELSON, MISSOURI.

Rose of the Quartiers, for the following reasons:

1st. Her body is deeper and ribs more sprung, which shows better digestion, it gives more room for more bulky feed which is necessary in the dairy cow.

2nd. Her udder is more prominent and milk veins larger; flank is more arched.

3rd. She is broader across the hips and pelvic arch more prominent.

4th. Her eyes are fuller and more prominent, which indicates a large nerve force. She has strong jaws, which is another indication of good digestion, and large nostrils, which show a deep breather.

R. T. ARGOL, TENNESSEE.

As you intimate, there appears to be very little difference between them, still, comparing the pictures, I can't avoid the belief that "Rose of the Quartiers" is the better cow, but you ask "why?" (without this a choice would be worthless). Because, first, the cow seems to have greater capacity, shown in the great depth of body. And the pelvic arch is much more pronounced than is the case with the other cow. The thighs are more incurving, and the udder does not seem to be as well formed in the other cow, nor does she have so large or tortuous milk veins.

While the other cow is of pronounced dairy form, yet she has some points that are against her; the tail sets on a level with her back and she has not the great depth of body as is the case with the other cow. I think there is little difference as to temperament, but I vote for "Rose of the Quartiers." Now give me the records of each cow, if they are obtainable.

M. S. WILCOX, NEW YORK.

My choice would be Rose. She is more wedge shape, finer body, fuller eye; (though that may be the way she stands) better shaped udder, milk veins more to my idea, and judging from picture a yellower and mellower skin.

Villet's Gem is a good looking cow to appearance, not so good milk veins, not so yellow in skin, body more steer like.

I judge her to be a good cow; her udder development is good.

FRANK E. WRIGHT, IOWA.

Am 13 years of age and like cows very much. I don't suppose I can select all of the points of excellence of the better cow. I think Rose of the Quartiers is the best cow. Her eyes seem to be brighter, her barrel larger, her flank arches higher, has better milk veins, ending in a larger eyelet and a better pelvic arch.

HENRY S. HOPKINS, IOWA.

It seems to me that Rose of Quartiers has the advantage over Villet's Gem.

She appears to have a better constitution, as indicated by the depth of chest, has also a greater heart girth. She is also deeper in the flank. Her barrel is deeper throughout. Then I think she has a slight advantage in the udder, it being a little fuller in front.

The line running up the rear of Villet's Gem's udder would lead me to believe that it is somewhat fleshy; however it is hard to judge of this from a photograph.

These I believe are the most prominent differences. I am curious to hear the criticisms of others.

H R. HEATH, INDIANA.

My choice of the two cows, if I were to buy either, from the photos, would be Rose of the Quartiers, for the reason that while she has full as good mammary development as the other, she also is nearer the wedge form, has larger digestive capacity and hence able to eat and assimmilate more food and give better results at the pail. The photos do not show the relative size or contour of milk veins and other parts essential to form a correct score in each cow, and while Rose does not show as large navel as the other (to which some attach considerable importance) I should still choose her of the two.

W. H. SEELYE, MICHIGAN.

As shown in the cuts, I would pay the most money for Rose of Quartiers, because she is the more economical producer as evinced by shortness of leg, depth of body with short middle piece, and large paunch.

I should expect a larger total yield for a term of years, as she has a higher flank, a higher pelvic arch, is more "cat hamed", i. e., has a larger place to put an udder and shows to be possessed of a less irritable disposition, and last but by no means least, I should expect her to be by far the better breeder, owing to the above reasons, combined with her general appearance of longevity and nerve force, as shown by her conformation and large eye, with strong umbilical development, with apparent greater heart and lung capacity.

W. C. HUNTINGTON, MICHIGAN.

I would unhesitatingly say Rose. Gem has too much daylight under her, and her belly is not large enough to yield large results through the year. She has a good udder, and from the fact that her picture has been sent to you, I conclude that she has done something to her credit, but will venture the opinion that the most creditable position of her performance, is usually in the first part of her period of lactation. I will also venture the opinion that her escutcheon is rather broad and well formed except that it is nearly parallel, being nearly or quite as wide at top as at bottom, while Rose's is much wider at bottom and may even be defective at top.

The position of each seems characteristic. Rose seems to have been caught just between swallowing one cud and raising the next. Her whole time and attention seem to be taken up with eating, drinking, ruminating and giving milk, while Gem has time to give lazy attention to what the photographer is doing.

CHARLES H. BRUSH.

Both cows are good ones. "Rose of the Quartiers" has nearly perfect dairy form, is a hearty rustling feeder with great storage and digestive capacity. "Villets Gem" has faulty line of backbone, narrow muzzle, limited storage capacity, is a delicate feeder, quite apt to be out of condition and "off her feed." These are the reasons why this young farmer believes "Rose of the Quarters" to be the more profitable cow.

J. R. ALLEN, PENNSYLVANIA.

Rose of the Quartiers is the best cow. She has the best dairy form, a fair wedge shape, with neat head, slim neck, deep

The *Dairy and Creamery* says the "heralds of dual-purpose propaganda are now singing very low," and it wittily adds: "They seem at last to have gone up against the point of Old Ike's philosophy, who advised his brethren, 'Never to strike at er step on er hoss-fly, in yo bar feet, till yo is keerful zamined dat ar hoss-fly, kase it mout be a honnit.' "

Cows give the thinnest milk just after calving. It becomes slightly richer during the next two weeks and then remains almost uniform in average quality for four or five months, after which it gradually increases in richness as the cow comes near to calving again, and by the ninth month from last calving is only one-seventh richer than it was during the earlier months.

FARM SEPARATORS.

To those who are looking for facts concerning the economy of the farm separator we would suggest a careful perusal of our Canadian letter by Mr. Wheaton, on page 314 of this issue. Some very interesting and instructive conclusions are there given. For instance, the saving on ten cows is shown to be $60 a year, saying nothing of the increased feeding value of the skim milk which is an important item. Sixty dollars is the interest on $1,000, at 6 per cent. So, if a man has ten cows, the farm separator gives him the advantage of a thousand dollars of additional capital. This fact illustrates very well the maxim of the great capitalist Stephen Girard, 'Wise methods are better than much money." Many a poor man with limited capital, by the use of intelligent methods is enabled to outstrip those who depend mainly alone on their capital. Verily, dairying is a work of the brain, as much as of the hand.

A BASE LIBEL REFUTED.

There exists in Chicago a publication calling itself the *Dairy World*. We seldom give it any attention, because it has neither character, circulation, knowledge of dairy affairs or disposition to honestly serve the dairy interests of that state or the nation. Why it exists, or what honest purpose it ever served in the promotion of the dairy industry, in any form whatever, is beyond mortal power to answer.

In consistent keeping with its past history and disposition, it has been making unprovoked and utterly untruthful assaults upon the National Dairy Union, and particularly upon its efficient secretary, Mr. Charles Y. Knight, editor of the *Chicago Produce*. These attacks are without any foundation whatever, except as prompted by envy or less honorable motive. Mr. Knight won to himself the confidence of the officers and members of the National Dairy Union by his zeal and efficiency in promoting the passage of the anti-color oleomargarine law in Illinois a year ago, and in the further defense of that law, and labor with others in securing additional legislation this year. In this Mr. Knight, unlike some other editors in that state, did his simple duty to the dairymen of Illinois and the consumers of dairy products everywhere, and he did it well.

He is backed by the entire dairy sentiment of his state, and has the confidence of the dealers in dairy products in Chicago and Elgin, and is supremely hated by every manufacturer of and dealer in counterfeit and fraudulent imitations of butter and cheese.

In addition to his efforts to bring the state of Illinois into line with other states, in this matter of pure food legislation, Mr. Knight, with the full endorsement of the National Dairy Union, has entered zealously into the work of doing what he can to secure the passage in Congress of the Davidson bill, for imposing a tax of ten cents per pound upon colored oleomargarine. This is, of course, not pleasing to the oleomargarine promoters, and, as in the past, they are doing what they can to oppose and belittle his efforts and influence. That they should easily succeed in securing the *Dairy World* as an ally or attorney in this treasonable work, is no matter of wonder whatever to those who are informed as to the situation. Nor are they surprised that it should publish, in furtherance of the plans of its oleomargarine friends, a mass of false and defamatory matter concerning Mr. Knight's efforts before the present legislature of Illinois, and accusing him of being in favor of "process butter."

No man of sense in the west, who has any information on the subject, will give the least credence to anything the *Dairy World* has said, and we are all greatly surprised to see the *Country Gentleman*, that was erstwhile very careful in such matters, reprint the falsehood, and by added words enroll itself among the traducers of Mr. Knight and the National Dairy Union. Had Luther H. Tucker been living, no such apostacy as this would have been possible.

Men may honestly differ upon the policy of the ten cent tax law, but for a paper like the *Country Gentleman* to descend to the level of the *Dairy World*, and enlist with such ready zeal in the furtherance of plans approved by the oleomargarine crowd, is both unexpected and inexplicable.

A HERD TEST FOR ONE YEAR.

HOARD'S DAIRYMAN is always gratified to lay before its readers any well authenticated records, which bring out in strong relief the true combination of all worthy dairy work—the man and the cow.

There are so many farmers who have not yet accepted the right standards of dairy thinking, and consequently do not attain to the most profitable results with their cows, that it becomes a useful thing to keep before our eyes what other men are actually doing.

The effect is different on different men. Some men will read a report over and because it exceeds very greatly what their cows are doing, they will throw it aside and claim it is all a lie. We have known hundreds of men do this.

Others will read it and thoughtfully study it, and say to themselves: "This man demonstrates what can be done. It is but common sense on my part to look into it and see if I cannot change my ideas, or my methods, or my cows, and do as well myself." That is the view the true student and true dairyman will take of it. We call attention to the following report of the year's work of a herd of Jersey cows, owned by Mr. Paul Cunningham, of Bolton, Mass.

MILK YIELD OF HERD FOR TWELVE MONTHS, ENDING DEC. 31ST, 1893.

Names.	*Age.*	*Milk.*	*Babcock test.*
	Years	Lbs.	%
Fenella	4	5,721	5.6
Ethel	4	4,853½	5.6
Miranda	6	7,300½	5.8
Sarci	6	5,654	5.
Ethel 4	10	5,170	5.6
Miss Wilton	12	5,648½	5.4
Duchess	6	6,848	5.8
Zillah	4	5,174	7.
Chloe	8	7,732½	5.4
Fairy	3	4,173	5.2
Thisbe	4	4,953	5.
Alice	7	5,391½	5.
Camelia	5	6,444½	5.
Mona	6	6,954	6.2
Rose	4	6,613	3.8
Jessica	7	6,989	5.2
Beatrice	4	6,602½	6.
Sybyl	4	5,424	5.4
Viking's Princess	6	6,173½	5.6
Iris	3	6,624	4.8
20 cows, av'ge per cow,		6,022 lbs. milk,	testing 5.42
9 " " "		6,901 " "	5.15
6 " " "		7,076 " "	5.53
4 " " "		7,244 " "	5.52
3 " " "		7,341 " "	5.8

Let us add a few figures to the above. The twenty cows averaged six thousand and twenty-two pounds of milk apiece, testing 5 42 per cent. This means that these cows averaged 326⅓ pounds of butter fat, or 380½ pounds of butter per cow.

Nine of the cows averaged 6,901 pounds of milk, with a test of 5.15 per cent, or a butter fat production of 355 pounds, being the equivalent of 414 pounds of butter per cow.

Six of the cows averaged 7,076 pounds of milk with a test of 5.53 per cent, a butter fat product of 391 pounds, equivalent to 456 pounds of butter.

Four of the cows averaged 7,244 pounds of milk, with a test of 5.52 per cent. This means a production of over 399 pounds of butter fat, or an equivalent of over 465 pounds of butter per cow.

Three of the cows averaged 7,341 pounds of milk, with a test of 5.8 per cent. This means a butter fat production per cow of 425 pounds of butter fat, or the equivalent of 495 pounds in butter.

Cows of this character were not bred on the hit or miss plan. They did not come through dual-purpose ideas. They are the product of dairy intelligence in breeding, dairy intelligence in feeding and handling.

To produce cows and manage them in a way that shall return such results, is what it means to be an up grade dairyman. The road is open to any man. The result depends upon what standard of intelligence he sets up in his mind. Every farmer has the choice, as well as the chance set before him.

Growing Ensilage Corn in the Maritime Provinces.

ED. HOARD'S DAIRYMAN:—The following letters give the manner of raising ensilage corn in the Maritime Provinces:

My method of growing ensilage corn is as follows: Early in the autumn I plow up a piece of good rich sod, I generally try and get as good a piece as I can, a field having a slight slope for drainage preferred.

The land is frequently harrowed afterwards thus killing any weeds or growth that might sprout. It also helps to rot the sod.

Early in the following spring this land is again ploughed and well harrowed. Stable manure well rotted at the rate of about 30 or 40 cart loads per acre is applied and well harrowed in until the land and manure are well mixed. About the 25th of May the corn, Peirce's Prolific, is sown in drills about 20 lbs. seed per acre is used.

If the land is not fine and mellow we roll it before drilling in the corn. We sow the corn in drills about 3 feet apart. Usually about a week or ten days after planting I put the Breed's corn cultivator over the land and continue using this cultivator until the corn is about 6 or 8 inches high. After that we use a Planet Jr. cultivator until corn is almost fit to harvest; we cut when the corn is matured on the stalk. It is cut into lengths about 1 inch long and elevated into silo. When silo has been allowed to settle, and again filled, we usually put on top about 6 inches of cut straw and chaff. We have had no difficulty in keeping it so far. The only trouble we have is we can't keep it long enough as the cattle eat it up always too soon.

We have had no trouble in getting cattle to eat it up clean. Sometimes when we buy a strange cow, or one that has not been used to ensilage, we have had to feed small quantities to her at first but the time soon comes when she will eat her share and will look for a little better measure of it. I find my cows do well on the feed. We always mix a little bran or crushed oats with it for milking cows and they seem to relish it. If any one is at all skeptical as to the cow liking it, he should come to our stables when we begin to feed it. You will hear the chains rattling and the cattle tugging at them, reaching out to get a sly bite as the attendant is passing. I consider it a cheap food. We can usually grow from 12 to 15 tons per acre. The cattle seem to like it and thrive on it, as our young stock and dry cows come out in the spring in fine condition.

I would not like to have to do without ensilage for my cattle, as I consider I cannot get any other crop to take its place giving the same quantity per acre at same cost.

I think farmers could increase their winter stock from 30 to 50 % by growing ensilage corn, provided they have suitable land.

I forgot to mention that I have grown corn on sod land prepared as above without any manure and had very good results but have had much better with stable manure applied.

I might also state that in 1897 I experimented a little with superphosphates and stable manure on big corn. I applied about 30 loads stable manure and about 300 lbs. superphosphate and potash on one strip and alongside I used 30 loads stable manure alone and on other side superphosphate and potash alone. As far as I could see, without weighing it, there was no perceptible increase where the fertilizers were used with the stable manure over the piece on which stable manure only was applied. The piece where the fertilizer alone was used was nearly but not quite equal to the stable manure alone. Of course if the land had been measured and the crop weighed a vast difference might have been perceived, but to the eye alone I could not see much difference over what I have stated.

E. R. BROW.

Charlottetown, P. E. I.

The method I have adopted for the cultivation of corn is as follows: I take a piece of stubble (oat) ground, plow it in the fall, and haul barnyard manure on it in the winter, and put it in composts.

In the spring I harrow the ground with a "spade" harrow, and then apply the manure at the rate of about twenty-five tons per acre, and plow it under. I then harrow the land thoroughly and mark it off in squares (with a marker I made myself) three feet apart each way. I then plant the corn with a hand planter, putting about four kernels in a hill. Two boys will plant six acres in a day.

As soon as the corn is nicely up, I go over the field with a light harrow, or a "Breed's weeder." A few days later, as soon as I can see the rows well, I start the horse hoe or cultivator, and keep it going at intervals of four or five days, going lengthwise and crosswise alternately, until the corn gets so high as to render it impossible. While we go very close to the hills with the cultivator, we have to go over it once with a hand hoe. But this is a very light job.

We plant about the last of May and the first of June and have to put in the silo (on account of frost) from the 10th to the 20th of September. On an average we get fifteen tons of corn, at the glazed stage, per acre.

We haul it to the barn and run it through the cutter and put it in the silo as fast as we cut it in the field.

This whole process from start to finish costs about $1 per ton for manual labor. I consider the ensilage worth $2 per ton in comparison with other foods. I use it as a supplementary food, and do not think in these provinces with the advantages we have for growing hay and roots, that it would be economical as a chief food for dairy stock.

The success of corn growing in these provinces depends first on your own special locality, and second on the facilities you have for carrying out the details of the work. There are a great many things to be said about it which cannot be said in one letter.

F. L. FULLER.

Hermanville, P. E. I.

SUMMARY.

It will be seen that Mr. Brow's method differs slightly to that of Mr. Fuller's; but only in the kind of land chosen. While Mr. Brow takes a pasture sod, Mr. Fuller takes an oat stubble. In his postscript, however, Mr Fuller says he intends trying a clover sod next year. In the manner of applying the manure, both gentlemen differ. Mr. Brow applies the manure on the surface, after plowing in the spring, and harrows it in, while Mr. Fuller plows the manure under. Here their methods differ considerably. But as both are able to grow fifteen tons per acre, it must be supposed that each are doing the very best under their particular circumstances.

It will be seen farther, that while one favors drilling, the other favors check-rows. No doubt the conditions in Nova Scotia are more cool and moist than in Prince Edward Island, and, by check-rowing the corn, the warmth and energizing effects of the sun can be the better utilized. Both lay great stress on after cultivation with such implements as Breed's weeder, Planet Jr., etc.

As to the economic value of the crop for dairy cows, a very high opinion is held, Mr Brow asserting that by growing corn ensilage, he is enabled to keep 30 to 50 per cent more cows; while Mr. Fuller says the crop can be grown and siloed for $1 per ton, and he considers it worth $2 for feeding Maritime farmers are therefore justified in making greater and repeated efforts to grow this really indispensable food for their dairy cows.

J. A. M.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade, aggregated 12,900 pounds. Bidding opened at 17½ cents, and 6,540 pounds were withdrawn on this bid.

The price offered advanced to 18 cents, but no sales were made. The Quotation Committee reported the market firm at 17½ cents.

The sales for the corresponding week of the three preceding years were as follows:

May 28, '98, 37,020 pounds of butter sold at 16c.
May 31, '97, 43,860 pounds of butter sold at 14@15c.
June 1, '96, 37,500 pounds of butter sold at 15½c.

The New York market was reported firm at 18½c.

H. C. B.

Elgin, Ill., May 29, '99.

Sand or Winter Vetch.

(*Vicia Villosa.*)

ED. HOARD'S DAIRYMAN:—Where so many contribute to the common good of all, to withhold any experience of value is not excusable, hence in reply to J. P. D.'s inquiry in DAIRYMAN of April 21st, will say that I have grown winter vetches for several years. They thrive alike on all kinds of soil and withstand the severest winter weather.

The seeds resemble the garden sweet peas and the vines are not very unlike sweet pea vines Their chief features of value are that they belong to the family of legumes, start up very early in spring and draw nitrogen from the air while their tap roots also bring up fertility from the subsoil.

Their chief value is for early soiling and for making into hay. They require a companion crop of rye to hold up and sustain the vines. If cut when the rye begins to form heads, both alike grow up again and form seed or another green crop.

The vetches add materially to the value of rye for fodder purposes, and if allowed to ripen the vetches (grain) are also rich in protein.

The vetches spoil rye straw for commercial purposes and make the gathering of the rye difficult and expensive, hence their chief value is confined to the dairyman and milk production.

J. H. NELLIS.

Mont. Co., N. Y.

There is No Disagreement Between Us.

ED. HOARD'S DAIRYMAN:—In reply to the article on breed and form, on page 212, April 28th, will say, that I admit I have a great deal to learn, for my opinion is that when a man thinks he knows it all, it is about time for him to get out of the dairy business.

My experience has taught me that it is a mistake to breed from a sire that came from a cow of dairy type, without she was from a dairy breed.

Do I understand from the reply the editor makes, he would as soon breed from a sire which was from a cow like our friend, John Gould's old "Slicker," which he calls a sport, as from one from a registered dam? While you might get once in awhile a good cow, the chances would be against it. If I knew I would be as successful with that sort of a sire, I could have saved some money on the prices of the sires I have bought.

But I think a man's life is too short to waste much time wandering about. Before I began to use a thoroughbred sire my experience was, the offspring was as likely to be poorer as to be as good as the sire and dam.

I am in the dairy business for what there is in it, do the feeding myself, and as much of the milking as is possible, and have, until of late, sold the butter from the dairy to families in the city. You can see my circumstances will not permit me to breed for the sake of a pedigree. I have cows in my herd that will give 34 pounds of milk in one day, that will test 6% butter fat. They are from grade Jersey cows, and a thoroughbred sire bought of A. H. Moore, of Cloverdale. If my experience had not taught me that I could not do as well with a grade sire, I would not have given the price I did for the calf, when I could have bought a grade calf for one-tenth the money, but was afraid I would have more cows that looked like steers, than I would have to look like cows. If anyone has a cow from a sport cow and a sport sire, that will produce the amount mentioned without the blood of some of the dairy families in their veins, I would like to hear from them. I have learned a great deal from HOARD'S DAIRYMAN and like it very much, but it is very fortunate for us not all to be of the same opinion, for if we were I am afraid we would not learn much.

Feasterville, Pa. W. H W.

W. H. W. apparently mieapprehends the language as well as the intent of the article to which he refers. The purpose of that article was to set forth the fact that when one is breeding for heifers to make profitable producers at the pail, he does not necessarily have to buy a bull with a fashionable, price-compelling pedigree. We did not advocate breeding from "sports" or grades.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

GLOSSARY.

The terms used in this department of HOARD'S DAIRYMAN have the following significance:

RATION.—The total allowance of feed for twenty-four hours.

DIGESTIBLE NUTRIENTS.—That portion of the organic matter which can be digested by the animal and does not pass off through the bowels as excrement.

PROTEIN.—That part of the digestible nutrients which goes to the formation of lean meat, ligaments, hair, horns and the casein (or curd) of milk. It is generally believed, also, that protein may be, and many times is, converted into the fat found in milk. The basis of protein is nitrogen, hence the protein elements are frequently termed the *nitrogenous* parts of the food. They are also called *albuminoids*.

CARBONYDRATES.—That part of the digestible nutrients which is the primary source of sustaining animal heat and furnishing the power for keeping the animal mechanism in operation. They are composed of the woody fibre of the plant and grain, and the starch, sugar, gums, etc., and in the published tables of chemical analyses are usually subdivided into the terms *crude fibre*, which is the least digestible portion of feeding stuffs and *nitrogen free-extract*, so-called because it does not contain any nitrogen.

ETHER EXTRACT.—That portion of the digestible nutrients which may be dissolved out of the food stuffs by ether. It is frequently called *crude fat*. Whether fat is actually digested and thus passed on into the circulatory system in a changed form or whether it is simply separated from the other elements and always maintains its identity is an unsettled problem. It can be used by the animal for maintaining the body temperature, and for this purpose is from 2.2 to 2.5 times more efficacious than the carbohydrates. It is maintained by some, that the fat in the milk comes, largely, from the crude fat in the food, but ithas been demonstrated that it is not absolutely necessary, for this purpose.

FEEDING STANDARDS FOR MILCH COWS.

	DIGESTIBLE NUTRIENTS		
Dry matter.	*Protein*	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12. to 15.0	0.5 to 0.8

WHEN TO CUT TIMOTHY AND CLOVER FOR HAY.

I have a meadow of timothy. When would you advise cutting, as I want to use it for my milch cows. I am retailing my milk in the city and therefore want to use the best milk producing feed. Would also like to know your opinion as to the time to cut clover meadow.

W. D. A.

Crawfordsville, Ind.

All kinds of forage intended for hay should be cut and cured before the seed matures or the stalk or stem becomes dry and woody, no matter whether it is clover, millet, oats, rye, or timothy. Clover and timothy are at their best for hay when in full bloom, but as it is impossible to commence and finish haying in a single day, or even in a week, we like to begin a little before all the heads are in blossom, so as to finish before too many have formed seed. These seeds are so small that stock cannot crush or grind them, and hence they pass off in the manure undigested. Cut the hay early, and the material which would otherwise go to mature the seeds remains in the stalks and is utilized by the animal.

TO DRIVE AWAY FLIES.

Kindly publish a good formula for keeping flies off of cows.

J. C. N.

Madison, N. Y.

You will find several compounds advertised in the DAIRYMAN, which are highly recommended.

If you wish to make your own mixture, we advise you to try the following:

Hebenstreit's Formula—Fish oil, 1 gallon; crude petroleum, ½ gallon; crude carbolic acid, 2 ounces.

Matteson's Formula—Fish oil, 3 quarts; petroleum, 1 quart; carbolic acid, 1 ounce.

One-half pint will go over twelve cows, and one application suffices for five to seven days. The common kerosene of commerce, such as is sold for illuminating purpose will answer in the place of the crude petroleum.

WARTS.

I have a Jersey cow in full flow of milk. Her teats are getting covered with small warts; they have been forming about a month; they stick out like little horns all over her teat. Can you tell me what to do to take them off?

W. S. N.

Winfield, Mo.

Try the castor oil remedy mentioned on page 220. We don't know that this is specifically better than other oil or grease. Rubbing with salt pork is one of the old remedies.

BARLEY OR CORN WITH ALFALFA.

Kindly inform me whether or no I can make a balanced ration from alfalfa hay, crushed barley and chopped alfalfa wet? Referring to your answer as to corn and alfalfa, May 12th, '99, should the chopped alfalfa and meal be given wet, or is it better to give it dry? My cows seem to eat it best wet.

HOWLAND.

Dona Ana, N. M.

Barley does not serve as good a purpose as corn, although it might, possibly, serve fairly well. Corn has both more carbohydrates and fat than barley, and these are especially needed with alfalfa hay. When there is quite a quantity of the chopped alfalfa mixed with the meal, it may be useful to moisten it, so that the meal will not sift to the bottom. See, also, answer to inquiry from Washington, in regard to chaffing hay and straw.

LUMP JAW CURES.

In Prof. Russell's article, "Plain Talks on Bacteria," pertaining to the disease of lump jaw, what is his opinion of the Fleming Bro's. cure?

When I came on this place five years ago, there was a well advanced case. I tried the iodide of potassium, but it was expensive and not reliable. I now have a valuable Guernsey bull that is just showing a lump. First noticed it May 1st.

Fleming Bros'. circular promises great things, but it was not mentioned by Prof. Russell. They advertise sure cure or no pay, but I don't like to advance money again, unless they are more reliable than some advertisers.

W. B. T.

Standing Stone, Pa.

The probabilities are that Prof. Russell knows nothing whatever, about the medicine referred to, and if he did, his position as an instructor in a State University would make it unseemly for him to single out one remedy for approval or disapproval. Professors, as well as editors, have to be exceptionally careful in such matters, as well in with holding condemnation, as in bestowing commendation.

The advertisement referred to has been published in the DAIRYMAN for a long time, and no complaint has reached us that the advertisers are not honorable gentlemen, and honestly abiding by the terms of their offer.

TO CORRECT LOOSENESS OF BOWELS.

Enclosed please find one dollar for the DAIRYMAN from the time it stopped. I like your plan of stopping the paper when the time expires.

Is there anything we can feed cows to correct looseness of the bowels this time of year?

We continue to feed about six pounds of corn meal and wheat bran, also hay.

Clifford, Penn. L. W. A.

Give less pasture and more hay, or let the trouble correct itself, as it will when the grass gets more substance.

SKIM MILK VEALS.

Can a veal calf be raised until six or eight weeks old on skim milk, with the addition of oil meal, and be considered by the butchers as good as one raised on whole milk? Or, in other words, would they buy it if they knew it was not a whole milk veal?

Woodland, Wash. F. A. H.

Butchers are very much like other people, ready to take advantage of every circumstance to cheapen the price of what they buy or enhance the price of what they sell. Good veal can be made from skim milk and grain, but not quite so choice in every respect perhaps as that raised on whole milk.

WHEN TO CUT RYE FOR HAY.

I have a piece of rye which I wish to cut and cure for fodder, as I have no silo at present. When should it be cut, and what is its feeding value when well cured, as compared with corn fodder and clover hay.

I am just as anxious to have my subscription renewed as you are to renew it, as we, as farmers, certainly need all the enlightenment we can obtain. In these times of close competition, ignorance and poverty must go together.

C. J. M.

Niagara Co., N. Y.

As to the proper time to cut rye for hay, see answer to W. S A., Crawfordsville, Indiana.

We give below the average per cent of digestible nutrients in the feed stuffs named, assuming that corn stover is meant:

	Dry Matter.	*Digestible Nutrients*		
		Protein.	Carbohydrates	Ether Extract
Corn stover	59.5	1.7	32.4	0.7
Oat hay	91.1	4.3	46.4	1.5
Rye hay	90.0	3.5	34.6	0.6

From this table it appears that rye hay, if cut at the proper time and well cured, would be worth considerably more than corn stover and approximately one-third less than oat hay.

WHICH IS THE BETTER COW?

(Continued from Page 307.)

bodied, with large stomach (capacity for food), large milk veins, and large square udder with a good milk capacity, and I think from the appearance of the picture, she has a sleek, glossy coat of hair and a large, full eye.

The other one has larger head, a smaller eye, thicker neck, slim body, small stomach, smaller milk veins, but a fair sized udder. But I think it is rather too fleshy and don't have the milk capacity the other one has.

CHARLES HALL, PENNSYLVANIA.

Premising that it is difficult when one has to decide only upon a picture, in my judgment, Rose is the better cow. She has the broader muzzle, the shorter legs, the slimmer neck, the more capacious body, the more prominent and tortuous milk veins, the better shaped udder forward, though not so well developed in rear, and from her general appearance I judge her to be the more persistent giver of richer milk. She also seems to be a cow of good constitution and great vitality. After all, I may be greatly mistaken.

J. CRONK, WISCONSIN.

I prefer Rose, because deeper through flank, larger belly, slimmer tail, smaller neck up to, or nearer, her head, a finer nose.

J. V. LOOMIS, WISCONSIN.

Rose of the Quartiers has greater capacity, a bigger place to manufacture milk, she is cut in deeper behind. I like that big, crooked milk vein, I like that "wedge shape," that short distance between the udder and front legs, those crooked hind legs, that big, prominent eye, looking out for more feed, that udder way up behind and way out in front.

The other cow is too long and too long legged. Rose will give more milk and milk through a longer period.

W. H. GILLETT, WISCONSIN.

Rose of the Quartiers has the dairy form, and we must go by that, although Villet's Gem has good points. Think she is too high over shoulders and not quite enough tank. Can't criticise her much.

CHARLES F. A. PIERCE, WISCONSIN.

In your last issue I notice you ask which is the better cow, Rose of the Quartiers or Villet's Gem, and as I have been a student of your paper in regard to dairy form discussions, I am going to give an opinion and see how they vary with others. This is my second year on a farm, so I do not expect great results in my attempt.

Rose of the Quartiers has some good dairy points which I think are lacking in Villet's Gem. First, she has a deeper barrel and better sprung ribs, which are most essential for a good dairy cow. Second, she has larger and more prominent milk veins, which extend well to the front. Third, she has large, prominent eyes and wide between them.

Villet's Gem also has excellent points, which are lacking in Rose of the Quartiers. First, she has light shoulders and sharp withers. Second, a prominent back bone. Third, a long, fairly deep, well sprung barrel. Fourth, is spare and lean which shows a persistent milking inclination. Fifth, a long, slender tail. Each cow has excellent dairy points, very much similar, such as a large udder, extending well to the front and up behind. High, arching flank. Fine neck and head and wide strong jaws. If I were to be given my choice of the two cows, I think I would not hesitate in choosing Villet's Gem.

S. H. JOINER, WISCONSIN.

The only way I could decide on two cows that were quite different on some points, and each one better than the other on some of those points, was to score the cuts and average the whole number of points. I did so and made out that Villet's Gem scored 79 and Rose scored 72—Villet's Gem having the best navel development, far the best tail and the indications from the cut showed the best rear part of udder, and the ribs and back bone showed loosest and boniest spinal column, indicating more nerve force.

W. T. HARBISON, MISSOURI.

I believe it would be hard to tell even by seeing the cows, let alone the pictures, but I *think* Rose of the Quartiers 8654 is rather the larger producer, but Villet's Gem 8664 will give the richest milk and at a less cost per pound of butter fat. She seems more on the bony order; and will turn most of her food to milk. I think they are both first-class dairy cows.

ED. HOARD'S DAIRYMAN:—When we sent you the cuts of the cattle that appeared in last week's issue, I wrote you what the two cows had done up to that time. Their records for the full year are as follows: Imp. Rose of the Quartiers 8654 gave 8,340 pounds milk, average monthly test 5.59% fat. Imp. Villet's Gem 8664 gave 9,265 pounds milk with an average monthly test of 5.58% fat. CHAS. H. ROYCE.

Ellerslie Farm, Rhinecliff, N. Y.

GROWING ALFALFA.

Two pieces of alfalfa, sown by us early this spring with oats, have come on finely, and the young plants are now two inches high. Knowing the nature of the plant to grow coarse and woody we took the precaution of seeding quite heavily, using at the rate of 30 pounds of seed to the acre.

The oats will be cut for hay when fairly in the milk, and the alfalfa given a chance to develop to its very best.

We are convinced that a hundred farmers ought to try alfalfa where one is doing it now.

A. E. Elford, of Holmesville, Canada, is a successful grower of alfalfa, and gives his method of proceedure as follows:

"About ten years ago we determined to try this new plant, we had read so much about in the American papers, and accordingly purchased a few pounds, and then made the same mistake so many have made and are making to-day—we mixed it with other grasses, so that if it did not come to anything we would still have something without it. For the first two years it did not amount to much, but as the clover and timothy grew thinner it grew thicker. When we harvested the mixture, the timothy and red clover were of good quality, but the alfalfa was more like small brush wood; nothing would eat it. It grew in clumps, brittle and good for nothing. This was an object lesson. Alfalfa will not associate with other grasses. Its habit of growth will not allow it; it is a very exclusive plant. We were not discouraged however with our trial. We experimented again and again, and this is our present method of procedure, which has given us the best results.

We sow with oats, barley or spring wheat, on soil *well worked* up and at the rate of 20 pounds to the acre. We sow in front of the seed drill, so as to have it covered sufficiently, then harrow and roll well. When we cut the grain the young alfalfa is frequently from twelve to fifteen inches high. It is disastrous to pasture it during the first fall; in fact it should not be pastured for the first three seasons, if possible not to do so.

Especially during the first winter the young plant requires all the mulch it can have.

We keep several paddocks near the barn for the purpose of soiling our cows. We generally commence cutting the first or second week in May. At that time we frequently have it two feet high. What we do not use as a soiling crop, we make into hay. For hay we cut as soon as the dew is off. It is preferable to cut no more than can be got into small coils before the dew falls in the evening. We commence to rake up and put into bunches when leaves are wilted; if allowed to lie too long the leaves fall off. Leave in small coil two or three days to sweat and cure. If weather threatens rain, put two or three coils into one. When sufficiently cured, haul to stack and salt lightly."

PUT BRAIN INTO THE WORK.

There are brainy farmers, who do brainy farming, and there are farmers whose effort is about all hard work, with but little mixture of brains. Ride through a farming section and note the difference. Here is a herd of fine cows, everyone of which shows the effect of the thought and brain of her owner. Across the road is a herd of accidents, bred without forethought, fed without intelligent purpose, and everything about them indicating that the thought and education of the day is wasted on that owner.

Two farms of 100 acres each are in our mind. Both lie side by side. One carries a herd of thirty-five fine cows, with an average return of $50 each at the neighboring creamery. The cash return of that farm, in pork, veals, poultry, hay and butter, is over $2,000. The owner is a student of his business. He puts thought, reading, study,—in a word, brain work into it.

The other farm, with its owner, its cows (only 12,) everything on it and about it is far away in the opposite direction. The owner is getting deeper in debt every year. The difference to start with was not capital; it was brains. The greater profit of the first farm is the reward of brains.

Prof. I. P. Roberts, of Cornell University speaking of the higher reward of brain work says:

"The man who fells trees in the forest may receive fifteen cents per hour, the man who controls the carriage of the great saw mill, and decides on the instant what shape and dimensions the lumber shall take, may receive twenty-five cents an hour for simply moving a little lever. A third may cause a piece of wood to take on the form of beauty for the great stair case, and may receive a dollar an hour."

The man who does the so-called hard work receives the least pay. Why? Because it is the least difficult—requires the least brain.

Every dairy farm in the land contains a chance for the same difference. There is a chance to use good thought or poor thought, good sense or poor sense, good intelligence or blank ignorance in everything we do.

The amazing difference in the profits of farmers who take milk to the same creamery show this. It is the difference in brains. There is hardly a creamery in the land but will show some one patron who makes a clean profit of from 50 to 100% over some other patron. Invariably, it will be found that the highest profit goes to the best brain work. Usually the man who gets the least, works the hardest.

A large herd of dairy cows was tested in central New York, and the owner of the herd was informed that about one-fourth of his cows were profitable, one-half paid their board bill, and one-fourth were kept at considerable loss. He was advised to reduce his herd, dispose of the unprofitable cows. His answer was: "But what will I do for cows?"

There are thousands of just such men keeping cows. Ask them to spend a little money for information, that shall give them a better judgment, and they will reply: "I can't afford it." What is the matter with such men? Is it not a most serious lack of intelligence?

SELLING OATS AND BUYING BRAN.

It is very evident that there are a great lot of farmers in the dairy business, and who really think they are in it for all that is out, who refuse to accept some of the first principles of profitable economy. They feed wastefully and to little profit because they will not accept the teachings of the best ability, best experiments and best experience that has been had. To illustrate what we mean: During the whole of the present winter we have noticed a large portion of the dairy farmers around Fort Atkinson hauling their corn and oats to the grinding mill, in the proportion of two of oats to one of corn. This mixture they fed their cows. When we asked them why they fed so expensive a food as oats they almost universally replied that they raised the oats. They seemed to have the idea that because they had raised the oats, somehow the cost of feeding them was less. We repeatedly took out our pencil and figured what the oats were worth by the ton and when once they had hauled them to the market to be ground the oats must be charged to the cow at full market rates. We often asked these men why they did not sell the oats and buy bran to mix with the corn? They seemed somehow averse to making any such deal, simply because they had raised the oats. On page 272, last week, John Gould puts the matter in a clear light when he says: "A ton of oats and $2 added for the grinding will to-day here buy 3,200 pounds of fine bran containing about 440 pounds of protein, while the ton of oats would have but 184 pounds of protein."

Now as Mr. Gould further says: "This is putting $12 against $26.50 with the further advantage of having the oat straw left." It is the men who never make a fine close study of feeding values and the best ways of feeding economy that make blunders like these.

Dairy farmers must learn that a great deal of valuable brains, study and experiment have been expended on this feeding question, and no man can afford to throw all this over his shoulder simply because he "has raised the oats."

THE SUBSCRIPTION PRICE REASONABLE.

We have often wondered that in this day when nearly every one seems to want to put down the price of everything they buy, that we should get so many letters of encouragement saying the subscription price of the DAIRYMAN was below the value the paper gave to the reader. Mr. P. H. Elkins, of Winston, N. C., who is educating himself to be a farmer, writes us as follows:

The subscription price of your paper is very reasonable indeed. It is worth one dollar a year to me to look at the different illustrations of cattle, silos, barns, creameries and other buildings. Add to this the

"Winter Finds Out What Summer Lays By."

Be it spring, summer, autumn or winter, someone in the family is "under the weather" from trouble originating in impure blood or irritated condition of the system.

All these, of whatever name, can be cured by the great blood purifier, Hood's Sarsaparilla. *It never disappoints.*

Abscesses—"I am past 54 and my good health is due to Hood's Sarsaparilla and Hood's Pills, which purified my blood and healed the ugly abscesses that troubled me." MRS. BRITTON C. ESTELL, Southard, N. J.

Dyspepsia—"My husband doctored a long time for dyspepsia with only temporary relief. The first bottle of Hood's Sarsaparilla helped and the second cured him. It cured my sick headaches." MRS. MARY A. CLARK, Wilmington, Vt.

Hood's Sarsaparilla
Never Disappoints

Hood's Pills cure liver ills; the non-irritating and only cathartic to take with Hood's Sarsaparilla.

Not a Preservative but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION MILK COOLER-AERATOR. It does its work perfectly and its use doesn't violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO., 67 Main Street, Cortland, N. Y.

experience of farmers all over the land, getting new ideas and greater light all the time on every subject pertaining to dairying and dairy farming.

Mr. Elkins appreciates "new ideas and greater light." They have a money value to him, because he sees how a man can make money by them. To such a man, and we are glad to say that most of our readers are such men, the paltry sum of one dollar is a mere trifle compared to what they can get from the DAIRYMAN in a year.

But to the farmer who knows it all, whom no man can instruct or stimulate, with whom navigation has closed forever, to such a man one dollar is just the same as thrown away, when he spends it for a paper like the DAIRYMAN. There are lots of such men keeping cows, all over the land, but "their eyes is sot" and we know of no earthly power that can make them see the truth of enlightened dairying as enlightened men see it.

RELATIVE IMPORTANCE OF BUTTER AND OLEOMARGARINE.

The Department of Agriculture estimate the production of butter, the present year, at 1,450,000,000 pounds, only a fraction of which goes abroad.

The production of oleomargarine for the fiscal year ending June 30th, 1898, was 55,388,000 pounds, which was an increase of 12,854,000 pounds over the year preceding. The production for the first nine months of this fiscal year was 63,000,000 pounds indicating a production for the year to June 1st, o f85,000,000. lbs. Ninety-nine pounds out of every hundred is eaten by the consumer under the supposition that it is butter. The recent testimony before Senator Mason's committee in Chicago proved beyond cavil that nearly the entire traffic in oleomargarine is a mass of deception from the time it is colored to represent butter until the time it is eaten by the consumer in the hotel or boarding house as butter.

The butter producers protest against being compelled to compete in the market against a fraud. They also protest against the consumer being obliged to pay butter prices for a colored swindle. They demand, if this business is going to continue, that the colored fraud shall pay 10 cents a pound tax to the United States government. Every farmer is vitally interested in securing this legislation. Every consumer of honest butter is equally interested. Every farmer who takes his milk to a cheese factory is also interested to a like amount, for if the oleomargarine drives butter out of the market, then the milk which was used in butter making will be compelled to go to the making of cheese, and there will come a swamp in the cheese market.

The milk producers of the land are vitally interested in keeping each branch of the dairy industry up to its best work.

The cheese factory proprietors and patrons should help along this fight just as zealously as the butter men. The National Dairy Union appeals to dairy farmers of all kinds, in particular, for financial assistance to carry on this fight.

So far it has appealed in vain to a great majority of the men who ought to help. A few have given liberally. Now is the time to aid the cause. Send 50 cents or $1.00, and receive a handsome badge in return.

SOILING CROPS.

Getting Ready for the Drouth.

Press Bulletin.

June 4, 1898, the College herd of thirty milking cows was being well fed on twenty acres of tame grass pasture from which an early crop of hay had been cut. June 19, this pasture not furnishing sufficient feed, forty-two acres of prairie grass pasture were added; and Aug. 19, these two pastures getting short, eleven acres of tame grass meadow were added, making seventy-three acres of pasture. With this amount it became necessary, the latter part of August, to begin feeding green kafir corn to keep up the flow of milk.

Contrast the College record, seventy-three acres of pasture for thirty cows, supplemented with green feed from the latter part of August, with that of a patron of the Manhattan creamery, who, having no pasture, turned his cows into a dry lot, cut green alfalfa and fed it to them, feeding ten head all they needed through the summer on four square rods less than two acres.

It pays to keep dairy cows supplied with full feed throughout the summer. From July 5th to August 16th, the College herd on full feed dropped 4½ per cent in daily milk yield, while eight herds in the vicinity of the College dropped 39 per cent in milk yield, because short pastures were not helped out with other feed.

A drouth may be expected some time in every summer. When it comes, the milk yield goes down all over the country and the price of dairy products goes up. Not many dairymen can add more pasture when the drouth comes, and the Kansas dairyman who can not, should without fail provide for feed to supplement short pastures, so as to insure a good milk flow when prices are the highest.

If the pasture does not become too scanty, the milk flow may be kept up by feeding grain, but for most dairymen this is too expensive. Liberal feeding of either green alfalfa or of alfalfa hay helps out short pasture, and both are cheap feeds where the dairyman has them. The cheapest and most convenient feed for summer drouth where the dairyman has a silo, is silage. The silo may be uncovered and the silage fed whenever other feed is short. If rains come and the grass again is sufficient feed, cover up the silo and wait for the next drouth or for winter.

Many dairymen have neither grain, alfalfa, nor silage, and should put in crops this spring that will supply green feed when the drouth comes. Plan today. Green wheat, green oats and green millet are good, but last only a short time. Begin cutting these crops as soon as the first heads appear, and continue until the stalks begin to harden. Sweet corn comes early, and is a good milk-producing feed, but the yield is too small Field corn, kafir corn and sorghum are the most profitable green crops for the Kansas dairyman who does not have alfalfa.

Below are given the average dates at which the various crops are available as green feed for dairy cows on the College farm:

Alfalfa—May 20 to September 30.
Wheat—June 1 to 15.
Oats—June 15 to 30.
Sweet corn—July 15 to 31.
Field corn—August 1 to September 15.
Sorghum—August 1 to September 30.
Kafir corn—August 1 to September 30.
Wheat—Fall pasture until ground freezes.

Many write asking how many acres of each crop is needed. The season, soil and thoroughness of cultivation affect the yield so much that we can not answer these questions. Green crops are most needed in dry summers, and in estimating the acreage required for a herd, plans should be made to have an ample supply for a very dry year. In a good year the surplus can be cured for winter. With these considerations, we have made the following estimate of the number of acres of each crop required to feed our thirty cows for the period during which the crop is available: Alfalfa 10, wheat 3, oats 3, sweet corn 3, field corn 4, sorghum 3, and kafir corn 3.—*Kansas Experiment Station.*
